Contents

- 1 Introduction & Motivation
- 2 The Reference Representation Language
- 3 Similarity Measures: Related Work
- 4 (Dis-)Similarity measures for DLs
- 5 Similarity-Based Inductive Learning Methods for the SW
- 6 Conclusions and Future Work Proposals

The Semantic Web

- **Semantic Web goal:** make the Web contents *machine-readable* and *processable* besides of human-readable
- **How to reach the SW goal:**
 - Adding meta-data to Web resources
 - Giving a *shareable and common semantics* to the meta-data by means of *ontologies*
- Ontological knowledge is generally described by the *Web Ontology Language (OWL)*
 - Supported by *well-founded semantics* of *DLs*
 - together with a series of available automated *reasoning services* allowing to derive logical consequences from an ontology

Motivations...

- The main approach used by inference services is *deductive reasoning*.
 - Helpful for computing class hierarchy, ontology consistency
- Conversely, tasks as *ontology learning, ontology population by assertions, ontology evaluation, ontology evolution, ontology mapping* require inferences able to return *higher general conclusions w.r.t. the premises*.
- **Inductive learning methods**, based on *inductive reasoning*, could be effectively used.

...Motivations

- Inductive reasoning generates *conclusions* that are of *greater generality* than the premises.
- The starting *premises* are specific, typically *facts or examples*
- *Conclusions* have *less certainty* than the premises.
- The **goal** is to formulate plausible *general assertions explaining the given facts* and that are able to *predict new facts*.

Goals

- Apply ML methods, particularly *instance based learning methods*, to the SW and SWS fields for
 - **improving reasoning** procedures
 - **inducing new knowledge** not logically derivable
 - **detecting** new concepts or concept drift in an ontology
 - improving **efficiency** and **effectiveness** of: *ontology population, query answering, service discovery and ranking*
- Most of the instance-based learning methods require (dis-)similarity measures
 - **Problem:** Similarity measures for complex concept descriptions (as those in the ontologies) is a field not deeply investigated [**Borgida et al. 2005**]
- **Solution:** Define new measures for ontological knowledge
 - able to cope with the OWL high expressive power

The Representation Language...

- *DLs* is the *theoretical foundation* of *OWL* language
 - standard de facto for the knowledge representation in the SW
- Knowledge representation by means of Description Logic
 - *ALC* logic is *mainly considered* as satisfactory compromise between *complexity* and *expressive power*

...The Representation Language

- Primitive *concepts* $N_C = \{C, D, \dots\}$: subsets of a domain
- Primitive *roles* $N_R = \{R, S, \dots\}$: binary relations on the domain
- *Interpretation* $\mathcal{I} = (\Delta^{\mathcal{I}}, \cdot^{\mathcal{I}})$ where
 $\Delta^{\mathcal{I}}$: *domain* of the interpretation and $\cdot^{\mathcal{I}}$: *interpretation function*:

Name	Syntax	Semantics
top concept	\top	$\Delta^{\mathcal{I}}$
bottom concept	\perp	\emptyset
concept	C	$C^{\mathcal{I}} \subseteq \Delta^{\mathcal{I}}$
full negation	$\neg C$	$\Delta^{\mathcal{I}} \setminus C^{\mathcal{I}}$
concept conjunction	$C_1 \sqcap C_2$	$C_1^{\mathcal{I}} \cap C_2^{\mathcal{I}}$
concept disjunction	$C_1 \sqcup C_2$	$C_1^{\mathcal{I}} \cup C_2^{\mathcal{I}}$
existential restriction	$\exists R.C$	$\{x \in \Delta^{\mathcal{I}} \mid \exists y \in \Delta^{\mathcal{I}} ((x, y) \in R^{\mathcal{I}} \wedge y \in C^{\mathcal{I}})\}$
universal restriction	$\forall R.C$	$\{x \in \Delta^{\mathcal{I}} \mid \forall y \in \Delta^{\mathcal{I}} ((x, y) \in R^{\mathcal{I}} \rightarrow y \in C^{\mathcal{I}})\}$

Knowledge Base & Subsumption

$$\mathcal{K} = \langle \mathcal{T}, \mathcal{A} \rangle$$

- *T-box* \mathcal{T} is a set of definitions $C \equiv D$, meaning $C^{\mathcal{I}} = D^{\mathcal{I}}$, where C is the concept name and D is a description
- *A-box* \mathcal{A} contains extensional assertions on concepts and roles e.g. $C(a)$ and $R(a, b)$, meaning, resp., that $a^{\mathcal{I}} \in C^{\mathcal{I}}$ and $(a^{\mathcal{I}}, b^{\mathcal{I}}) \in R^{\mathcal{I}}$.

Subsumption

Given two concept descriptions C and D , C *subsumes* D , denoted by $C \sqsubseteq D$, iff for every interpretation \mathcal{I} , it holds that $C^{\mathcal{I}} \supseteq D^{\mathcal{I}}$

Examples

An instance of concept definition:

$\text{Father} \equiv \text{Male} \sqcap \exists \text{hasChild}.\text{Person}$

"a father is a male (person) that has some persons as his children"

The following are instances of simple assertions:

$\text{Male}(\text{Leonardo})$, $\text{Male}(\text{Vito})$, $\text{hasChild}(\text{Leonardo}, \text{Vito})$

Supposing $\text{Male} \sqsubseteq \text{Person}$:

$\text{Person}(\text{Leonardo})$, $\text{Person}(\text{Vito})$ and then $\text{Father}(\text{Leonardo})$

Other related concepts: $\text{Parent} \equiv \text{Person} \sqcap \exists \text{hasChild}.\text{Person}$ and
 $\text{FatherWithoutSons} \equiv \text{Male} \sqcap \exists \text{hasChild}.\text{Person} \sqcap \forall \text{hasChild} . (\neg \text{Male})$

It is easy to see that the following relationships hold:

$\text{Parent} \sqsubseteq \text{Father}$ and $\text{Father} \sqsubseteq \text{FatherWithoutSons}$.

Other Inference Services

least common subsumer is the most specific concept that subsumes a set of considered concepts

instance checking decide whether an individual is an instance of a concept

retrieval find all individuals instance of a concept

realization problem finding the concepts which an individual belongs to, especially the most specific one, if any:

most specific concept

Given an A-Box \mathcal{A} and an individual a , the *most specific concept* of a w.r.t. \mathcal{A} is the concept C , denoted $\text{MSC}_{\mathcal{A}}(a)$, such that $\mathcal{A} \models C(a)$ and $C \sqsubseteq D$, $\forall D$ such that $\mathcal{A} \models D(a)$.

Classify Measure Definition Approaches

- **Dimension Representation:** feature vectors, strings, sets, trees, clauses...
- **Dimension Computation:** geometric models, feature matching, semantic relations, Information Content, alignment and transformational models, contextual information...
- Distinction: *Propositional* and *Relational* setting
 - analysis of computational models

Propositional Setting: Measures based on Geometric Model

- **Propositional Setting:** Data are represented as n-tuple of fixed length in an n-dimensional space
- **Geometric Model:** objects are seen as *points in an n-dimensional space*.
 - The *similarity* between a pair of objects is considered *inversely related to the distance* between two objects points in the space.
 - Best known distance measures: *Minkowski* measure, *Manhattan* measure, *Euclidean* measure.
- Applied to vectors whose *features* are *all continuous*.

Kernel Functions...

- *Similarity functions able to work with high dimensional feature spaces.*
- Developed jointly with **kernel methods**: efficient learning algorithms realized for solving classification, regression and clustering problems in high dimensional feature spaces.
 - **Kernel machine**: encapsulates the learning task
 - **kernel function**: encapsulates the hypothesis language

...Kernel Functions

- **Kernel method** can be very efficient because *they map, by means of a kernel function*, the original feature space into a higher-dimensional space, where the learning task is simplified.
- A *kernel function* performs such a *mapping implicitly*
 - **Any set that admits a positive definite kernel can be embedded into a linear space** [Aronszs 1950]

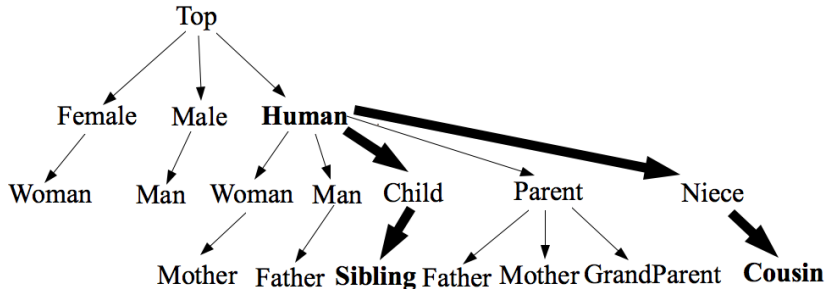

Similarity Measures based on Feature Matching Model

- **Features** can be of **different types**: binary, nominal, ordinal
- *Tversky's Similarity Measure*: based on the notion of *contrast model*
 - **common features** tend to **increase** the perceived similarity of two concepts
 - **feature differences** tend to **diminish** perceived similarity
 - feature *commonalities increase* perceived similarity *more than feature differences* can diminish it
 - it is assumed that *all features have the same importance*
- **Measures in propositional setting are not able to capture expressive relationships among data** that typically characterize most complex languages.

Relational Setting: Measures Based on Semantic Relations

- Also called **Path distance measures** [Bright,94]
- Measure the *similarity* value between single words (*elementary concepts*)
- concepts (words) are organized in a *taxonomy* using hypernym/hyponym and synonym links.
- the measure is a (weighted) *count of the links* in the path *between two terms* w.r.t. the most specific ancestor
 - terms with a **few links** separating them are semantically **similar**
 - terms with **many links** between them have **less similar** meanings
 - link counts are weighted because different relationships have different implications for semantic similarity.

Measures Based on Semantic Relations: Example

Measures Based on Semantic Relations: WEAKNESS

- the similarity value is subjective due to the taxonomic ad-hoc representation
- the introduction of new terms can change similarity values
- the similarity measures cannot be applied directly to the knowledge representation
 - it needs of an intermediate step which is building the term taxonomy structure
- only "linguistic" relations among terms are considered; there are not relations whose semantics models domain

Measures Based on Information Content...

- Measure semantic similarity of concepts in an *is-a* taxonomy by the use of notion of *Information Content (IC)* [Resnik,99]
- Concepts similarity is given by the shared information
 - The *shared information* is represented by a *highly specific super-concept* that subsumes both concepts
- *Similarity value* is given by the *IC of the least common super-concept*
 - *IC for a concept is determined* considering the probability that an instance belongs to the concept

...Measures Based on Information Content

- Use a criterion similar to those used in *path distance measures*,
- Differently from *path distance measures*, the use of probabilities **avoids the unreliability of counting edge** when changing in the hierarchy occur
- **The considered relation among concepts is only is-a relation**
 - **more semantically expressive relations cannot be considered**

Relational Kernel Functions...

- Motivated by the necessity of solving real-world problems in an efficient way.
- Best known relational kernel function: the **convolution kernel** [Haussler 1999]
- *Basic idea*: the semantics of a composite object can be captured by a relation R between the object and its parts.
 - The kernel is composed of kernels defined on different parts.
- *Obtained by composing existing kernels by a certain sum over products*, exploiting the closure properties of the class of positive definite functions.

$$k(x, y) = \sum_{\vec{x} \in R^{-1}(x), \vec{y} \in R^{-1}(y)} \prod_{d=1}^D k_d(x_d, y_d) \quad (1)$$

...Relational Kernel Functions

- The term "convolution kernel" refers to a class of kernels that can be formulated as shown in (1).
- Exploiting convolution kernel, string kernels, tree kernel, graph kernels etc.. have been defined.
- The **advantage of convolution kernels** is that they are **very general** and can be applied in several situations.
- **Drawback:** due to their generality, a significant amount of work is required to adapt convolution kernel to a specific problem
 - **Choosing R in real-world applications is a non-trivial task**

Similarity Measures for Very Low Expressive DLs...

- Measures for complex concept descriptions [Borgida et al. 2005]
 - A DL allowing only *concept conjunction* is considered (propositional DL)
- **Feature Matching Approach:**
 - features are represented by atomic concepts
 - An ordinary concept is the conjunction of its features
 - *Set intersection* and *difference* corresponds to the *LCS* and *concept difference*
- **Semantic Network Model and IC models**
 - The *most specific ancestor* is given by the *LCS*

...Similarity Measures for Very Low Expressive DLs

OPEN PROBLEMS in considering most expressive DLs:

- What is a *feature* in most expressive DLs?
 - i.e. $(\leq 3R)$, $(\leq 4R)$ and $(\leq 9R)$ are three different features?
or $(\leq 3R)$, $(\leq 4R)$ are more similar w.r.t $(\leq 9R)$?
 - How to assess similarity in presence of role restrictions? i.e.
 $\forall R.(\forall R.A)$ and $\forall R.A$
- Key problem in *network-based measures*: how to assign a useful size for the various concepts in the description?
- *IC-based model*: how to compute the value $p(C)$ for assessing the IC?

Why New Measures

- **Already defined similarity/dissimilarity measures cannot be directly applied to ontological knowledge**
 - They define similarity value between *atomic concepts*
 - They are defined for *representation less expressive* than ontology representation
 - They *cannot exploit all the expressiveness* of the *ontological* representation
 - There are **no measure for assessing similarity between individuals**
- **Defining new measures that are really semantic is necessary**

Similarity Measure between Concepts: Needs

- Necessity to have a measure really based on Semantics
- Considering [Tversky'77]:
 - common features tend to increase the perceived similarity of two concepts
 - feature differences tend to diminish perceived similarity
 - feature commonalities increase perceived similarity more than feature differences can diminish it
- The proposed similarity measure is:

Similarity Measure between Concepts

Definition [d'Amato et al. @ CILC 2005]: Let \mathcal{L} be the set of all concepts in \mathcal{ALC} and let \mathcal{A} be an A-Box with canonical interpretation \mathcal{I} . The *Semantic Similarity Measure* s is a function

$$s : \mathcal{L} \times \mathcal{L} \mapsto [0, 1]$$

defined as follows:

$$s(C, D) = \frac{|I^{\mathcal{I}}|}{|C^{\mathcal{I}}| + |D^{\mathcal{I}}| - |I^{\mathcal{I}}|} \cdot \max\left(\frac{|I^{\mathcal{I}}|}{|C^{\mathcal{I}}|}, \frac{|I^{\mathcal{I}}|}{|D^{\mathcal{I}}|}\right)$$

where $I = C \sqcap D$ and $(\cdot)^{\mathcal{I}}$ computes the concept extension wrt the interpretation \mathcal{I} .

Similarity Measure: Meaning

- If $C \equiv D$ ($C \sqsubseteq D$ and $D \sqsubseteq C$) then $s(C, D) = 1$, i.e. the maximum value of the similarity is assigned.
- If $C \sqcap D = \perp$ then $s(C, D) = 0$, i.e. the minimum similarity value is assigned because concepts are totally different.
- Otherwise $s(C, D) \in]0, 1[$. The *similarity* value is *proportional* to the *overlapping* amount of the concept extensions *reduced by* a quantity representing how the two concepts are near to the overlap. This means considering similarity not as an absolute value but as weighted w.r.t. *a degree of non-similarity*.

Similarity Measure: Example...

Primitive Concepts: $N_C = \{\text{Female, Male, Human}\}$.

Primitive Roles:

$N_R = \{\text{HasChild, HasParent, HasGrandParent, HasUncle}\}$.

$\mathcal{T} = \{ \text{Woman} \equiv \text{Human} \sqcap \text{Female}; \text{Man} \equiv \text{Human} \sqcap \text{Male}$

$\text{Parent} \equiv \text{Human} \sqcap \exists \text{HasChild.Human}$

$\text{Mother} \equiv \text{Woman} \sqcap \text{Parent} \exists \text{HasChild.Human}$

$\text{Father} \equiv \text{Man} \sqcap \text{Parent}$

$\text{Child} \equiv \text{Human} \sqcap \exists \text{HasParent.Parent}$

$\text{Grandparent} \equiv \text{Parent} \sqcap \exists \text{HasChild} . (\exists \text{HasChild.Human})$

$\text{Sibling} \equiv \text{Child} \sqcap \exists \text{HasParent} . (\exists \text{HasChild} \geq 2)$

$\text{Niece} \equiv \text{Human} \sqcap \exists \text{HasGrandParent.Parent} \sqcup \exists \text{HasUncle.Uncle}$

$\text{Cousin} \equiv \text{Niece} \sqcap \exists \text{HasUncle} . (\exists \text{HasChild.Human}) \}$.

...Similarity Measure: Example...

$\mathcal{A} = \{\text{Woman}(\text{Claudia}), \text{Woman}(\text{Tiziana}), \text{Father}(\text{Leonardo}), \text{Father}(\text{Antonio}),$
 $\text{Father}(\text{AntonioB}), \text{Mother}(\text{Maria}), \text{Mother}(\text{Giovanna}), \text{Child}(\text{Valentina}),$
 $\text{Sibling}(\text{Martina}), \text{Sibling}(\text{Vito}), \text{HasParent}(\text{Claudia}, \text{Giovanna}),$
 $\text{HasParent}(\text{Leonardo}, \text{AntonioB}), \text{HasParent}(\text{Martina}, \text{Maria}),$
 $\text{HasParent}(\text{Giovanna}, \text{Antonio}), \text{HasParent}(\text{Vito}, \text{AntonioB}),$
 $\text{HasParent}(\text{Tiziana}, \text{Giovanna}), \text{HasParent}(\text{Tiziana}, \text{Leonardo}),$
 $\text{HasParent}(\text{Valentina}, \text{Maria}), \text{HasParent}(\text{Maria}, \text{Antonio}), \text{HasSibling}(\text{Leonardo}, \text{Vito}),$
 $\text{HasSibling}(\text{Martina}, \text{Valentina}), \text{HasSibling}(\text{Giovanna}, \text{Maria}),$
 $\text{HasSibling}(\text{Vito}, \text{Leonardo}), \text{HasSibling}(\text{Tiziana}, \text{Claudia}),$
 $\text{HasSibling}(\text{Valentina}, \text{Martina}), \text{HasChild}(\text{Leonardo}, \text{Tiziana}),$
 $\text{HasChild}(\text{Antonio}, \text{Giovanna}), \text{HasChild}(\text{Antonio}, \text{Maria}), \text{HasChild}(\text{Giovanna}, \text{Tiziana}),$
 $\text{HasChild}(\text{Giovanna}, \text{Claudia}), \text{HasChild}(\text{AntonioB}, \text{Vito}),$
 $\text{HasChild}(\text{AntonioB}, \text{Leonardo}), \text{HasChild}(\text{Maria}, \text{Valentina}),$
 $\text{HasUncle}(\text{Martina}, \text{Giovanna}), \text{HasUncle}(\text{Valentina}, \text{Giovanna})\}$

...Similarity Measure: Example

$$\begin{aligned}
 s(\text{Grandparent}, \text{Father}) &= \frac{|(\text{Grandparent} \sqcap \text{Father})^{\mathcal{I}}|}{|\text{Grandparent}^{\mathcal{I}}| + |\text{Father}^{\mathcal{I}}| - |(\text{Grandparent} \sqcap \text{Father})^{\mathcal{I}}|} \cdot \\
 &\quad \cdot \max\left(\frac{|(\text{Grandparent} \sqcap \text{Father})^{\mathcal{I}}|}{|\text{Grandparent}^{\mathcal{I}}|}, \frac{|(\text{Grandparent} \sqcap \text{Father})^{\mathcal{I}}|}{|\text{Father}^{\mathcal{I}}|}\right) = \\
 &= \frac{2}{2 + 3 - 2} \cdot \max\left(\frac{2}{2}, \frac{2}{3}\right) = 0.67
 \end{aligned}$$

Similarity Measure between Individuals

Let c and d two individuals in a given A-Box.

We can consider $C^* = \text{MSC}^*(c)$ and $D^* = \text{MSC}^*(d)$:

$$s(c, d) := s(C^*, D^*) = s(\text{MSC}^*(c), \text{MSC}^*(d))$$

Analogously:

$$\forall a : s(c, D) := s(\text{MSC}^*(c), D)$$

Similarity Measure: Conclusions...

- s is a *Semantic* Similarity measure
 - It uses only *semantic inference* (Instance Checking) for determining similarity values
 - It does *not make use of the syntactic structure* of the concept descriptions
 - It does *not add complexity besides of* the complexity of *used inference operator* ($IChk$ that is PSPACE in \mathcal{ALC})
- Dissimilarity Measure is defined using the set theory and reasoning operators
 - **It uses a numerical approach but it is applied to symbolic representations**

...Similarity Measure: Conclusions

- Experimental evaluations demonstrate that s works satisfying when it is applied between concepts
- s applied to individuals is often zero even in case of similar individuals
 - The MSC^* is so specific that often covers only the considered individual and not similar individuals
- The *new idea* is to measure the similarity (dissimilarity) of the subconcepts that build the MSC^* concepts in order to find their similarity (dissimilarity)
 - *Intuition*: Concepts defined by almost the same sub-concepts will be probably similar.

MSC^* : AnExample

$MSC^*(Claudia) = \text{Woman} \sqcap \text{Sibling} \sqcap \exists \text{HasParent}(\text{Mother} \sqcap \text{Sibling} \sqcap \exists \text{HasSibling}(\text{C1}) \sqcap \exists \text{HasParent}(\text{C2}) \sqcap \exists \text{HasChild}(\text{C3}))$
 $\text{C1} \equiv \text{Mother} \sqcap \text{Sibling} \sqcap \exists \text{HasParent}(\text{Father} \sqcap \text{Parent}) \sqcap \exists \text{HasChild}(\text{Cousin} \sqcap \exists \text{HasSibling}(\text{Cousin} \sqcap \text{Sibling} \sqcap \exists \text{HasSibling}.\top))$
 $\text{C2} \equiv \text{Father} \sqcap \exists \text{HasChild}(\text{Mother} \sqcap \text{Sibling})$
 $\text{C3} \equiv \text{Woman} \sqcap \text{Sibling} \sqcap \exists \text{HasSibling}.\top \sqcap \exists \text{HasParent}(\text{C4})$
 $\text{C4} \equiv \text{Father} \sqcap \text{Sibling} \sqcap \exists \text{HasSibling}(\text{Uncle} \sqcap \text{Sibling} \sqcap \exists \text{HasParent}(\text{Father} \sqcap \text{Grandparent})) \sqcap \exists \text{HasParent}(\text{Father} \sqcap \text{Grandparent} \sqcap \exists \text{HasChild}(\text{Uncle} \sqcap \text{Sibling}))$

\mathcal{ALC} Normal Form

D is in \mathcal{ALC} *normal form* iff $D \equiv \perp$ or $D \equiv \top$ or if
 $D = D_1 \sqcup \dots \sqcup D_n$ ($\forall i = 1, \dots, n, D_i \not\equiv \perp$) with

$$D_i = \bigcap_{A \in \text{prim}(D_i)} A \sqcap \bigcap_{R \in N_R} \left[\forall R. \text{val}_R(D_i) \sqcap \bigcap_{E \in \text{ex}_R(D_i)} \exists R. E \right]$$

where:

$\text{prim}(C)$ set of all (negated) atoms occurring at C 's top-level

$\text{val}_R(C)$ conjunction $C_1 \sqcap \dots \sqcap C_n$ in the value restriction on R , if any (o.w. $\text{val}_R(C) = \top$);

$\text{ex}_R(C)$ set of concepts in the value restriction of the role R

For any R , every sub-description in $\text{ex}_R(D_i)$ and $\text{val}_R(D_i)$ is in normal form.

Overlap Function

Definition [d'Amato et al. @ KCAP 2005 Workshop]:

$\mathcal{L} = \mathcal{ALC}/\equiv$ the set of all concepts in \mathcal{ALC} normal form

\mathcal{I} canonical interpretation of A-Box \mathcal{A}

$f : \mathcal{L} \times \mathcal{L} \mapsto R^+$ defined $\forall C = \bigsqcup_{i=1}^n C_i$ and $D = \bigsqcup_{j=1}^m D_j$ in $\mathcal{L} \equiv$

$$f(C, D) := f_{\sqcup}(C, D) = \begin{cases} \infty & C \equiv D \\ 0 & C \sqcap D \equiv \perp \\ \max_{\substack{i=1, \dots, n \\ j=1, \dots, m}} f_{\sqcap}(C_i, D_j) & \text{o.w.} \end{cases}$$

$$f_{\sqcap}(C_i, D_j) := f_P(\text{prim}(C_i), \text{prim}(D_j)) + f_V(C_i, D_j) + f_{\exists}(C_i, D_j)$$

Overlap Function / II

$$f_P(\text{prim}(C_i), \text{prim}(D_j)) := \frac{|(\text{prim}(C_i))^{\mathcal{I}} \cup (\text{prim}(D_j))^{\mathcal{I}}|}{|((\text{prim}(C_i))^{\mathcal{I}} \cup (\text{prim}(D_j))^{\mathcal{I}}) \setminus ((\text{prim}(C_i))^{\mathcal{I}} \cap (\text{prim}(D_j))^{\mathcal{I}})|}$$

$$f_P(\text{prim}(C_i), \text{prim}(D_j)) := \infty \text{ if } (\text{prim}(C_i))^{\mathcal{I}} = (\text{prim}(D_j))^{\mathcal{I}}$$

$$f_{\forall}(C_i, D_j) := \sum_{R \in N_R} f_{\sqcup}(\text{val}_R(C_i), \text{val}_R(D_j))$$

$$f_{\exists}(C_i, D_j) := \sum_{R \in N_R} \sum_{k=1}^N \max_{p=1, \dots, M} f_{\sqcup}(C_i^k, D_j^p)$$

where $C_i^k \in \text{ex}_R(C_i)$ and $D_j^p \in \text{ex}_R(D_j)$ and wlog.

$N = |\text{ex}_R(C_i)| \geq |\text{ex}_R(D_j)| = M$, otherwise exchange N with M

Dissimilarity Measure

The *dissimilarity measure* d is a function $d : \mathcal{L} \times \mathcal{L} \mapsto [0, 1]$ such that, for all $C = \bigsqcup_{i=1}^n C_i$ and $D = \bigsqcup_{j=1}^m D_j$ concept descriptions in \mathcal{ALC} normal form:

$$d(C, D) := \left\{ \begin{array}{l} 0 \\ 1 \\ \frac{1}{f(C, D)} \end{array} \right. \left| \begin{array}{l} f(C, D) = \infty \\ f(C, D) = 0 \\ \text{otherwise} \end{array} \right.$$

where f is the function overlapping

Discussion

- If $C \equiv D$ (namely $C \sqsubseteq D$ e $D \sqsubseteq C$) (semantic equivalence)
 $d(C, D) = 0$, rather d assigns the minimum value
- If $C \sqcap D \equiv \perp$ then $d(C, D) = 1$, rather d assigns the maximum value because concepts involved are totally different
- Otherwise $d(C, D) \in]0, 1[$ rather *dissimilarity is inversely proportional to the quantity of concept overlap*, measured considering the entire definitions and their subconcepts.

Dissimilarity Measure: example...

$$C \equiv A_2 \sqcap \exists R.B_1 \sqcap \forall T.(\forall Q.(A_4 \sqcap B_5)) \sqcup A_1$$

$$D \equiv A_1 \sqcap B_2 \sqcap \exists R.A_3 \sqcap \exists R.B_2 \sqcap \forall S.B_3 \sqcap \forall T.(B_6 \sqcap B_4) \sqcup B_2$$

where A_i and B_j are all primitive concepts.

$$C_1 := A_2 \sqcap \exists R.B_1 \sqcap \forall T.(\forall Q.(A_4 \sqcap B_5))$$

$$D_1 := A_1 \sqcap B_2 \sqcap \exists R.A_3 \sqcap \exists R.B_2 \sqcap \forall S.B_3 \sqcap \forall T.(B_6 \sqcap B_4)$$

$$f(C, D) := f_{\sqcup}(C, D) = \max\{ f_{\sqcap}(C_1, D_1), f_{\sqcap}(C_1, B_2), \\ f_{\sqcap}(A_1, D_1), f_{\sqcap}(A_1, B_2) \}$$

...Dissimilarity Measure: example...

For brevity, we consider the computation of $f_{\sqcap}(C_1, D_1)$.

$$f_{\sqcap}(C_1, D_1) = f_P(\text{prim}(C_1), \text{prim}(D_1)) + f_{\forall}(C_1, D_1) + f_{\exists}(C_1, D_1)$$

Suppose that $(A_2)^{\mathcal{I}} \neq (A_1 \sqcap B_2)^{\mathcal{I}}$. Then:

$$\begin{aligned} f_P(C_1, D_1) &= f_P(\text{prim}(C_1), \text{prim}(D_1)) \\ &= f_P(A_2, A_1 \sqcap B_2) \\ &= \frac{|I|}{|I \setminus ((A_2)^{\mathcal{I}} \cap (A_1 \sqcap B_2)^{\mathcal{I}})|} \end{aligned}$$

where $I := (A_2)^{\mathcal{I}} \cup (A_1 \sqcap B_2)^{\mathcal{I}}$

...Dissimilarity Measure: example...

In order to calculate f_{\forall} it is important to note that

- There are two different role at the same level T and S
- So the summation over the different roles is made by two terms.

$$\begin{aligned}
 f_{\forall}(C_1, D_1) &= \sum_{R \in N_R} f_{\sqcup}(\text{val}_R(C_1), \text{val}_R(D_1)) = \\
 &= f_{\sqcup}(\text{val}_T(C_1), \text{val}_T(D_1)) + \\
 &+ f_{\sqcup}(\text{val}_S(C_1), \text{val}_S(D_1)) = \\
 &= f_{\sqcup}(\forall Q.(A_4 \sqcap B_5), B_6 \sqcap B_4) + f_{\sqcup}(\top, B_3)
 \end{aligned}$$

...Dissimilarity Measure: example

In order to calculate f_{\exists} it is important to note that

- There is only a single one role R so the first summation of its definition collapses in a single element
- N and M (numbers of existential concept descriptions w.r.t the same role (R)) are $N = 2$ and $M = 1$
 - So we have to find the max value of a single element, that can be simplified.

$$\begin{aligned}
 f_{\exists}(C_1, D_1) &= \sum_{k=1}^2 f_{\sqcup}(\text{ex}_R(C_1), \text{ex}_R(D_1^k)) = \\
 &= f_{\sqcup}(B_1, A_3) + f_{\sqcup}(B_1, B_2)
 \end{aligned}$$

Dissimilarity Measure: Conclusions

- Experimental evaluations demonstrate that d *works satisfying* both for concepts and individuals
- *However*, for complex descriptions (such as MSC^*), deeply nested subconcepts could increase the dissimilarity value
- **New idea:** differentiate the weight of the subconcepts wrt their levels in the descriptions for determining the final dissimilarity value
 - **Solve the problem:** *how differences in concept structure might impact concept (dis-)similarity? i.e. considering the series $dist(B, B \sqcap A)$, $dist(B, B \sqcap \forall R.A)$, $dist(B, B \sqcap \forall R.\forall R.A)$ this should become smaller since more deeply nested restrictions ought to represent smaller differences."* [Borgida et al. 2005]

The weighted Dissimilarity Measure

Overlap Function Definition [d'Amato et al. @ SWAP 2005]:

$\mathcal{L} = \mathcal{ALC} / \equiv$ the set of all concepts in \mathcal{ALC} normal form

\mathcal{I} canonical interpretation of A-Box \mathcal{A}

$f : \mathcal{L} \times \mathcal{L} \mapsto \mathbb{R}^+$ defined $\forall C = \bigsqcup_{i=1}^n C_i$ and $D = \bigsqcup_{j=1}^m D_j$ in $\mathcal{L} \equiv$

$$f(C, D) := f_{\sqcup}(C, D) = \begin{cases} |\Delta| \\ 0 \\ 1 + \lambda \cdot \max_{\substack{i=1, \dots, n \\ j=1, \dots, m}} f_{\sqcap}(C_i, D_j) \end{cases} \left| \begin{array}{l} C \equiv D \\ C \sqcap D \equiv \perp \\ \text{o.w.} \end{array} \right.$$

$$f_{\sqcap}(C_i, D_j) := f_P(\text{prim}(C_i), \text{prim}(D_j)) + f_{\forall}(C_i, D_j) + f_{\exists}(C_i, D_j)$$

Looking toward Information Content: Motivation

- *The use of Information Content* is presented as *the most effective way for measuring complex concept descriptions* [Borgida et al. 2005]
- The necessity of considering concepts in normal form for computing their (dis-)similarity is argued [Borgida et al. 2005]
 - *confirmation* of the used approach in the previous measure
- **A dissimilarity measure for complex descriptions grounded on IC has been defined**
 - \mathcal{ALC} concepts in *normal form*
 - based on the *structure and semantics* of the concepts.
 - *elicits the underlying semantics*, by querying the KB for assessing the *IC* of concept descriptions w.r.t. the KB
 - *extension for considering individuals*

Information Content: Definition

- A measure of concept (dis)similarity can be derived from the notion of *Information Content* (IC)
- IC depends on the probability of an individual to belong to a certain concept
 - $IC(C) = -\log pr(C)$
- In order to approximate the probability for a concept C , it is possible to recur to its extension wrt the considered ABox.
 - $pr(C) = |C^I|/|\Delta^I|$
- A function for measuring the *IC variation* between concepts is defined

Function Definition /I

[d'Amato et al. @ SAC 2006] $\mathcal{L} = \mathcal{ALC}/\equiv$ the set of all concepts in \mathcal{ALC} normal form

\mathcal{I} canonical interpretation of A-Box \mathcal{A}

$f : \mathcal{L} \times \mathcal{L} \mapsto R^+$ defined $\forall C = \bigsqcup_{i=1}^n C_i$ and $D = \bigsqcup_{j=1}^m D_j$ in $\mathcal{L} \equiv$

$$f(C, D) := f_{\sqcup}(C, D) = \left\{ \begin{array}{c} 0 \\ \infty \\ \max_{\substack{i=1, \dots, n \\ j=1, \dots, m}} f_{\sqcap}(C_i, D_j) \end{array} \right| \begin{array}{l} C \equiv D \\ C \sqcap D \equiv \perp \\ \text{o.w.} \end{array}$$

$$f_{\sqcap}(C_i, D_j) := f_P(\text{prim}(C_i), \text{prim}(D_j)) + f_{\forall}(C_i, D_j) + f_{\exists}(C_i, D_j)$$

Function Definition / II

$$f_P(\text{prim}(C_i), \text{prim}(D_j)) := \begin{cases} \infty & \text{if } \text{prim}(C_i) \sqcap \text{prim}(D_j) \equiv \perp \\ \frac{IC(\text{prim}(C_i) \sqcap \text{prim}(D_j)) + 1}{IC(LCS(\text{prim}(C_i), \text{prim}(D_j))) + 1} & \text{o.w.} \end{cases}$$

$$f_V(C_i, D_j) := \sum_{R \in N_R} f_{\sqcup}(\text{val}_R(C_i), \text{val}_R(D_j))$$

$$f_{\exists}(C_i, D_j) := \sum_{R \in N_R} \sum_{k=1}^N \max_{p=1, \dots, M} f_{\sqcup}(C_i^k, D_j^p)$$

where $C_i^k \in \text{ex}_R(C_i)$ and $D_j^p \in \text{ex}_R(D_j)$ and wlog.

$N = |\text{ex}_R(C_i)| \geq |\text{ex}_R(D_j)| = M$, otherwise exchange N with M

Dissimilarity Measure: Definition

The *dissimilarity measure* d is a function $d : \mathcal{L} \times \mathcal{L} \mapsto [0, 1]$ such that, for all $C = \bigsqcup_{i=1}^n C_i$ and $D = \bigsqcup_{j=1}^m D_j$ concept descriptions in \mathcal{ALC} normal form:

$$d(C, D) := \begin{cases} 0 & f(C, D) = 0 \\ 1 & f(C, D) = \infty \\ 1 - \frac{1}{f(C, D)} & \text{otherwise} \end{cases}$$

where f is the function defined previously

Discussion

- $d(C, D) = 0$ iff $IC=0$ iff $C \equiv D$ (semantic equivalence) rather d assigns the minimum value
- $d(C, D) = 1$ iff $IC \rightarrow \infty$ iff $C \sqcap D \equiv \perp$, rather d assigns the maximum value because concepts involved are totally different
- Otherwise $d(C, D) \in]0, 1[$ rather d tends to 0 if IC tends to 0; d tends to 1 if IC tends to infinity

The GCS-based Similarity Measure: Rationale

Two concepts are more similar as much their extensions are similar

- the similarity value is given by the variation of the number of instances in the concept extensions w.r.t. the number of instances in the extension of their common super-concept
 - Common super-concept \Rightarrow the GCS of the concepts [Baader et al. 2004]

Fig. 1. Concepts $C \equiv$ credit-card-payment, $D \equiv$ debit-card-payment are similar as the extension of their GCS \equiv card-payment does not include many other instances besides of those

Fig. 2. Concepts $C \equiv$ car-transfer, $D \equiv$ debit-card-payment are different as the extension of their GCS \equiv service includes many other instances besides of those of the extension of C

The GCS-based Similarity Measure: Definition

Definition: [d'Amato et al. @ SMR2 WS at ISWC 2007]

Let \mathcal{T} be an \mathcal{ALC} TBox. For all C and D $\mathcal{ALC}(T)$ -concept descriptions, the function $s : \mathcal{ALC}(T) \times \mathcal{ALC}(T) \rightarrow [0, 1]$ is a *Semantic Similarity Measure* defined as follow:

$$s(C, D) = \frac{\min(|C'|, |D'|)}{|(GCS(C, D))'|} \cdot \left(1 - \frac{|(GCS(C, D))'|}{|\Delta'|}\right) \cdot \left(1 - \frac{\min(|C'|, |D'|)}{|(GCS(C, D))'|}\right)$$

where $(\cdot)'$ computes the concept extension w.r.t. the interpretation I (canonical interpretation).

Relational Kernel Function: Motivation

- Kernel functions jointly with a kernel method.
- *Advantage*: 1) efficiency; 2) the learning algorithm and the kernel are almost completely independent.
 - An efficient *algorithm for attribute-value* instance spaces *can be converted into one* suitable *for structured spaces* by merely *replacing the kernel function*.
- A **kernel function for \mathcal{ALC} normal form concept descriptions** has been defined.
 - Based both on the *syntactic structure* (exploiting the *convolution* kernel [Haussler 1999]) and on the *semantics*, derived from the ABox.

Kernel Definition/I

[Fanizzi et al. @ ISMIS 2006] Given the space X of \mathcal{ALC} normal form concept descriptions, $D_1 = \bigsqcup_{i=1}^n C_i^1$ and $D_2 = \bigsqcup_{j=1}^m C_j^2$ in X , and an interpretation \mathcal{I} , the \mathcal{ALC} *kernel* based on \mathcal{I} is the function $k_{\mathcal{I}} : X \times X \mapsto \mathbb{R}$ inductively defined as follows.

disjunctive descriptions:

$$k_{\mathcal{I}}(D_1, D_2) = \lambda \sum_{i=1}^n \sum_{j=1}^m k_{\mathcal{I}}(C_i^1, C_j^2) \quad \text{with } \lambda \in]0, 1]$$

conjunctive descriptions:

$$k_{\mathcal{I}}(C^1, C^2) = \prod_{\substack{P_1 \in \text{prim}(C^1) \\ P_2 \in \text{prim}(C^2)}} k_{\mathcal{I}}(P_1, P_2) \cdot \prod_{R \in N_R} k_{\mathcal{I}}(\text{val}_R(C^1), \text{val}_R(C^2)) \cdot \prod_{R \in N_R} \sum_{\substack{C_i^1 \in \text{ex}_R(C^1) \\ C_j^2 \in \text{ex}_R(C^2)}} k_{\mathcal{I}}(C_i^1, C_j^2)$$

Kernel Definition/II

primitive concepts:

$$k_{\mathcal{I}}(P_1, P_2) = \frac{k_{\text{set}}(P_1^{\mathcal{I}}, P_2^{\mathcal{I}})}{|\Delta^{\mathcal{I}}|} = \frac{|P_1^{\mathcal{I}} \cap P_2^{\mathcal{I}}|}{|\Delta^{\mathcal{I}}|}$$

where k_{set} is the kernel for set structures [Gaertner 2004]. This case includes also the negation of primitive concepts using set difference: $(\neg P)^{\mathcal{I}} = \Delta^{\mathcal{I}} \setminus P^{\mathcal{I}}$

Kernel function: Discussion

- The kernel function can be extended to the case of individuals/concept
- The kernel is *valid*
 - The function is symmetric
 - The function is closed under multiplication and sum of valid kernel (kernel set).
- Being the kernel valid, and *induced distance measure* (metric) can be obtained [Haussler 1999]

$$d_I(C, D) = \sqrt{k_I(C, C) - 2k_I(C, D) + k_I(D, D)}$$

Semi-Distance Measure: Motivations

- Most of the presented measures are grounded on concept structures \Rightarrow hardly scalable w.r.t. most expressive DLs
- **IDEA:** *on a semantic level, similar individuals should behave similarly w.r.t. the same concepts*
- Following HDD [**Sebag 1997**]: individuals can be compared on the grounds of their behavior w.r.t. a given set of hypotheses $F = \{F_1, F_2, \dots, F_m\}$, that is a collection of (primitive or defined) concept descriptions
 - F stands as a group of *discriminating features* expressed in the considered language
- As such, the new measure *totally depends on semantic* aspects of the individuals in the KB

Semantic Semi-Distance Measure: Definition

[Fanizzi et al. @ DL 2007] Let $\mathcal{K} = \langle \mathcal{T}, \mathcal{A} \rangle$ be a KB and let $\text{Ind}(\mathcal{A})$ be the set of the individuals in \mathcal{A} . Given sets of concept descriptions $F = \{F_1, F_2, \dots, F_m\}$ in \mathcal{T} , a *family of semi-distance functions* $d_p^F : \text{Ind}(\mathcal{A}) \times \text{Ind}(\mathcal{A}) \mapsto \mathbb{R}$ is defined as follows:

$$\forall a, b \in \text{Ind}(\mathcal{A}) \quad d_p^F(a, b) := \frac{1}{m} \left[\sum_{i=1}^m |\pi_i(a) - \pi_i(b)|^p \right]^{1/p}$$

where $p > 0$ and $\forall i \in \{1, \dots, m\}$ the *projection function* π_i is defined by:

$$\forall a \in \text{Ind}(\mathcal{A}) \quad \pi_i(a) = \begin{cases} 1 & F_i(a) \in \mathcal{A} \quad (\mathcal{K} \models F_i(a)) \\ 0 & \neg F_i(a) \in \mathcal{A} \quad (\mathcal{K} \models \neg F_i(a)) \\ \frac{1}{2} & \text{otherwise} \end{cases}$$

Distance Measure: Example

$\mathcal{T} = \{ \text{Female} \equiv \neg \text{Male}, \text{Parent} \equiv \forall \text{child}.\text{Being} \sqcap \exists \text{child}.\text{Being},$
 $\text{Father} \equiv \text{Male} \sqcap \text{Parent},$
 $\text{FatherWithoutSons} \equiv \text{Father} \sqcap \forall \text{child}.\text{Female} \}$

$\mathcal{A} = \{ \text{Being}(\text{ZEUS}), \text{Being}(\text{APOLLO}), \text{Being}(\text{HERCULES}), \text{Being}(\text{HERA}),$
 $\text{Male}(\text{ZEUS}), \text{Male}(\text{APOLLO}), \text{Male}(\text{HERCULES}),$
 $\text{Parent}(\text{ZEUS}), \text{Parent}(\text{APOLLO}), \neg \text{Father}(\text{HERA}),$
 $\text{God}(\text{ZEUS}), \text{God}(\text{APOLLO}), \text{God}(\text{HERA}), \neg \text{God}(\text{HERCULES}),$
 $\text{hasChild}(\text{ZEUS}, \text{APOLLO}), \text{hasChild}(\text{HERA}, \text{APOLLO}),$
 $\text{hasChild}(\text{ZEUS}, \text{HERCULES}), \}$

Suppose $F = \{F_1, F_2, F_3, F_4\} = \{\text{Male}, \text{God}, \text{Parent}, \text{FatherWithoutSons}\}.$

Let us compute the distances (with $p = 1$):

$d_1^F(\text{HERCULES}, \text{ZEUS}) =$

$(|1 - 1| + |0 - 1| + |1/2 - 1| + |1/2 - 0|) / 4 = 1/2$

$d_1^F(\text{HERA}, \text{HERCULES}) =$

$(|0 - 1| + |1 - 0| + |1 - 1/2| + |0 - 1/2|) / 4 = 3/4$

Semi-Distance Measure: Discussion 1/2

- The measure is a semi-distance
 - $d_p(a, b) \geq 0$ and $d_p(a, b) = 0$ if $a = b$
 - $d_p(a, b) = d_p(b, a)$
 - $d_p(a, c) \leq d_p(a, b) + d_p(b, c)$
- *it does not guaranties* that if $d_p^F(a, b) = 0 \Rightarrow a = b$

Semi-Distance Measure: Discussion 2/2

- *More similar* the considered *individuals are*, more similar the project function values are $\Rightarrow d_p^F \simeq 0$
- *More different* the considered *individuals are*, more different the projection values are \Rightarrow the value of d_p^F will increase
- The measure does not depend on any specific constructor of the language \Rightarrow *Language Independent Measure*
- The measure complexity mainly depends from the complexity of the *Instance Checking* operator for the chosen DL
 - $Compl(d_p^F) = |F| \cdot 2 \cdot Compl(IChk)$
- **Optimal discriminating feature set could be learned**

Measure Optimization: Feature Selection

- **Implicit assumption:** F represents a sufficient number of (possibly redundant) features that are really able to discriminate different individuals
- The choice of the concepts to be included in F could be crucial for the correct behavior of the measure
 - a "good" feature committee may discern individuals better
 - a smaller committee yields more efficiency when computing the distance
 - Proposed optimization algorithms that are able to find/build optimal discriminating concept committees [Fanizzi et al. @ DL 2007 and @ ICSC 2007]
- *Experimentally obtained good results by using the very set of both primitive and defined concepts in the ontology*

Goals for using Inductive Learning Methods in the SW

Instance-base classifier for

- Semi-automatize the A-Box population task
- Induce new knowledge not logically derivable
- Improve concept retrieval and query answering inference services
- *Realized algorithms*
 - Relational K-NN
 - Relational kernel embedded in a SVM

Unsupervised learning methods for

- Improve the service discovery task
 - Exploiting (dis-)similarity measures for improving the ranking of the retrieved services
- Detect new concepts and concept drift in an ontology

Classical K-NN algorithm...

...Classical K-NN algorithm...

...Classical K-NN algorithm

- Generally applied to feature vector representation
- In classification phase it is assumed that each training and test example belong to a single class, so classes are considered to be disjoint
- An implicit *Closed World Assumption* is made

Difficulties in applying K-NN to Ontological Knowledge

To apply K-NN for classifying individual asserted in an ontological knowledge base

- 1 It has to find a way for applying K-NN to a most complex and expressive knowledge representation
- 2 It is not possible to assume disjointness of classes. Individuals in an ontology can belong to more than one class (concept).
- 3 The classification process has to cope with the *Open World Assumption* charactering Semantic Web area

Choices for applying K-NN to Ontological Knowledge

[d'Amato et al. @ URSW Workshop at ISWC 2006]

- ❶ To have similarity and dissimilarity measures applicable to ontological knowledge allows applying K-NN to this kind of knowledge representation
- ❷ A new classification procedure is adopted, decomposing the multi-class classification problem into smaller binary classification problems (one per target concept).
 - For each individual to classify w.r.t each class (concept), classification returns $\{-1, +1\}$
- ❸ A third value 0 representing unknown information is added in the classification results $\{-1, 0, +1\}$
- ❹ Hence a majority voting criterion is applied

Measures for Evaluating Experiments

- **Performance evaluated** by *comparing the procedure responses to those returned by a standard reasoner* (Pellet)
- **Predictive Accuracy:** measures the number of correctly classified individuals w.r.t. overall number of individuals.
- **Omission Error Rate:** measures the amount of unlabelled individuals $C(x_q) = 0$ with respect to a certain concept C_j while they are instances of C_j in the KB.
- **Commission Error Rate:** measures the amount of individuals labelled as instances of the negation of the target concept C_j , while they belong to C_j or vice-versa.
- **Induction Rate:** measures the amount of individuals that were found to belong to a concept or its negation, while this information is not derivable from the KB.

Experimentation Evaluation

Results (average \pm std-dev.) using the measure based on overlap.

	Match Rate	Commission Rate	Omission Rate	Induction Rate
FAMILY	.654 \pm .174	.000 \pm .000	.231 \pm .173	.115 \pm .107
FSM	.974 \pm .044	.026 \pm .044	.000 \pm .000	.000 \pm .000

S.-W.-M.	.820 \pm .241	.000 \pm .000	.064 \pm .111	.116 \pm .246
FINANCIAL	.807 \pm .091	.024 \pm .076	.000 \pm .001	.169 \pm .046

Experimentation: Discussion...

- For every ontology, the *commission error is almost null*; the classifier almost never makes critical mistakes
- **FSM Ontology**: the classifier always assigns individuals to the correct concepts; *it is never capable to induce new knowledge*
 - Because individuals are all instances of a single concept and are involved in a few roles, so MSCs are very similar and so the amount of information they convey is very low

...Experimentation: Discussion...

SURFACE-WATER-MODEL and FINANCIAL Ontology

- The classifier always assigns individuals to the correct concepts
 - Because most of individuals are instances of a single concept
- Induction rate is not null so *new knowledge is induced*. This is mainly due to
 - some *concepts* that are declared to be *mutually disjoint*
 - some *individuals* are *involved in relations*

...Experimentation: Discussion

FAMILY Ontology

- Predictive Accuracy is not so high and Omission Error not null
 - Because instances are more irregularly spread over the classes, so computed MSCs are often very different provoking sometimes incorrect classifications (weakness on K-NN algorithm)
- No Commission Error (but only omission error)
- The *Classifier* is able to *induce new knowledge* that is *not derivable*

Comparing the Measures

- The **measure based on IC** *poorly classifies concepts* that have *less information* in the ontology
 - *The measure based on IC is less able*, w.r.t. the measure based on overlap, *to classify concepts* correctly, when they have *few information* (instance and object properties involved);
- **Comparable behavior** when *enough information* is available
- **Inducted knowledge can be used for**
 - *semi-automatize ABox population*
 - *improving concept retrieval*

Experiments: Querying the KB exploiting relational K-NN

Setting

- 15 queries randomly generated by conjunctions/disjunctions of primitive or defined concepts of each ontology.
- **Classification of all individuals in each ontology w.r.t the query concept**
- Performance evaluated by comparing the procedure responses to those returned by a standard reasoner (Pellet) employed as a baseline.
- The *Semi-distance measure* has been used
 - *All concepts in ontology have been employed as feature set F*

Ontologies employed in the experiments

<i>ontology</i>	<i>#concepts</i>	<i>#obj. prop</i>	<i>#data prop</i>	<i>#individuals</i>
FSM	20	10	7	37
S.-W.-M.	19	9	1	115
SCIENCE	74	70	40	331
NTN	47	27	8	676
FINANCIAL	60	17	0	652

Experimentation: Results

	<i>match</i> <i>rate</i>	<i>commission</i> <i>rate</i>	<i>omission</i> <i>rate</i>	<i>induction</i> <i>rate</i>
FSM	97.7 \pm 3.00	2.30 \pm 3.00	0.00 \pm 0.00	0.00 \pm 0.00
S.-W.-M.	99.9 \pm 0.20	0.00 \pm 0.00	0.10 \pm 0.20	0.00 \pm 0.00
SCIENCE	99.8 \pm 0.50	0.00 \pm 0.00	0.20 \pm 0.10	0.00 \pm 0.00
FINANCIAL	90.4 \pm 24.6	9.40 \pm 24.5	0.10 \pm 0.10	0.10 \pm 0.20
NTN	99.9 \pm 0.10	0.00 \pm 7.60	0.10 \pm 0.00	0.00 \pm 0.10

Experimentation: Discussion

- Very low commission error: almost never the classifier makes critical mistakes
- Very high match rate 95%(more than the previous measures 80%) \Rightarrow Highly comparable with the reasoner
- Very low induction rate \Rightarrow Less able (w.r.t. previous measures) to induce new knowledge
- *Lower match rate for FINANCIAL ontology as data are not enough sparse*
- The usage of all concepts for the set F made the measure accurate, which is the reason why the procedure resulted conservative as regards inducing new assertions.

Testing the Effect of the Variation of F on the Measure

- *Expected result*: with an increasing number of considered hypotheses for F , the accuracy of the measure would increase accordingly.
- **Considered ontology**: *Financial* as it is the most populated
- Experiment repeated with an increasing percentage of concepts randomly selected for F from the ontology.
- Results confirm the hypothesis
- **Similar results for the other ontologies**

Experimentation: Results

% of concepts	match	commission	omission	Induction
20%	79.1	20.7	0.00	0.20
40%	96.1	03.9	0.00	0.00
50%	97.2	02.8	0.00	0.00
70%	97.4	02.6	0.00	0.00
100%	98.0	02.0	0.00	0.00

SVM and Relational Kernel Function for the SW

- A SMV is a classifier that, by means of kernel function, implicitly maps the training data into a higher dimensional feature space where they can be classified using a linear classifier
 - A SVM from the LIBSVM library has been considered
- *Learning Problem*: Given an ontology, classify all its individuals w.r.t. all concepts in the ontology [**Fanizzi et al. @ KES 2007**]
- *Problems to solve*: 1) Implicit CWA; 2) Assumption of class disjointness
- *Solutions*: Decomposing the classification problem is a set of ternary classification problems $\{+1, 0, -1\}$, for each concept of the ontology

Experiments: Discussion

- High matching rate
- Induction Rate not null \Rightarrow new knowledge is induced
- For every ontology, the commission error is quite low \Rightarrow the classifier does not make critical mistakes
 - Not null for UNIVERSITY and FSM ontologies \Rightarrow They have the lowest number of individuals
 - There is not enough information for separating the feature space producing a correct classification
- **In general** *the match rate increases with the increase of the number of individuals in the ontology*
 - Consequently the commission error rate decreases
- **Similar results by using the classifier for querying the KB**

Basics on Clustering Methods

Clustering methods: unsupervised inductive learning methods that organize a collection of unlabeled resources into meaningful clusters such that

- intra-cluster *similarity* is high
- inter-cluster *similarity* is low

Conceptual Clustering: Related Works

- **Few** algorithms for Conceptual Clustering (CC) with multi-relational representations [Stepp & Michalski, 86]
- **Fewer** dealing with the SW standard representations and their semantics
 - KLUSTER [Kietz & Morik, 94]
 - CSKA [Fanizzi et al., 04]
 - Produce a *flat output*
 - *Suffer from noise* in the data
- **Proposal** of new (agglomerative/divisional) hierarchical CC algorithms that
 - are **similarity-based** \Rightarrow *noise tolerant*
 - produce a *hierarchy of clusters*
 - can be used for *detecting new concepts or concept drift* and for *improving the efficiency of the service (resource) discovery* task

A Clustering method for Managing Ontologies

- Ontologies evolve over the time.
 - *New instances are asserted*
 - New concepts are defined
- **Concept Drift**
 - the change of a known concept w.r.t. the evidence provided by new annotated individuals that may be made available over time
- **Novelty Detection**
 - isolated cluster in the search space that requires to be defined through new emerging concepts to be added to the KB
- **Conceptual clustering methods can be used for automatically discover them [Fanizzi et al. @ ESWC 2008]**

Clustering Algorithm: Characteristics

- *Hierarchical* algorithm \Rightarrow returns a *hierarchy of clusters*
- Inspired to the K-Means algorithm
 - Defined for feature vectors representation where features are only numerical and the notion of the cluster *centroids* (weighted average of points in a cluster) is used for partition
- Exploits the notion of **medoid** (drawn from the PAM algorithm)
 - **central element in a group of instances**

$$m = \text{medoid}(C) = \underset{a \in C}{\operatorname{argmin}} \sum_{j=1}^n d(a, a_j)$$

Running the Clustering Algorithm

- *Level-wise* (number of level given in input, it is the number of clusters that we want to obtain): find the **worst cluster** on that level that has to be split
 - *worst cluster* \Leftrightarrow having the *least average inner similarity* (*cohesiveness*)
 - **select** the two **most dissimilar element** in the cluster *as medoid*
- split the cluster iterating (till convergence)
 - **distribute individuals** to either partition on the grounds of their similarity w.r.t. the medoids
 - given this bipartition, **compute the new medoids** *for either cluster*
 - **STOP when** the two generated medoids are equal to the previous ones (stable configuration) **or when** the maximum number of iteration is reached

Clustering Algorithm: Main Idea

Clustering Algorithm: Discussion

- As for the PAM algorithm, our algorithm can be used with any specified similarity measure
 - Others algorithms do not allow such a flexibility (only Euclidean measure is allowed)
 - Flexibility important for using the algorithm for finding clusters w.r.t. different criteria
 - e.g. researcher in biological applications are interested in grouping correlated elements and also anti-correlated elements
- *Medoids* are *more robust* in presence of *outliers* w.r.t. centroids that are weighted average of points in a cluster
 - The medoid is dictated by the location of predominant fraction of points inside a cluster
 - Robustness particularly important in the SW context where there can be many elements do not belonging exactly to any cluster due to the OWA

Conceptual Clustering Step

For DLs that allow for (approximations of) the msc and lcs , (e.g. \mathcal{ALC} or $\mathcal{AL}\mathcal{E}$):

- given a cluster $node_j$,
 - $\forall a_i \in node_j$ compute $M_i := msc(a_i)$ w.r.t. the ABox \mathcal{A}
 - let $MSCs_j := \{M_i | a_i \in node_j\}$
- $node_j$ *intensional description* $lcs(MSCs_j)$

Alternatively a *Supervised Learning phase* can be used

- Learn a definition for $node_j$ whose individuals represent the positive examples while the individuals in the other clusters at the same level are the negative example
- More complex algorithms for concepts learning in some DLs may be employed ([Esposito,04] [Lehmann,06])

Automated Concept Drift and Novelty Detection

If *new annotated individuals are made available* they have to be integrated in the clustering model

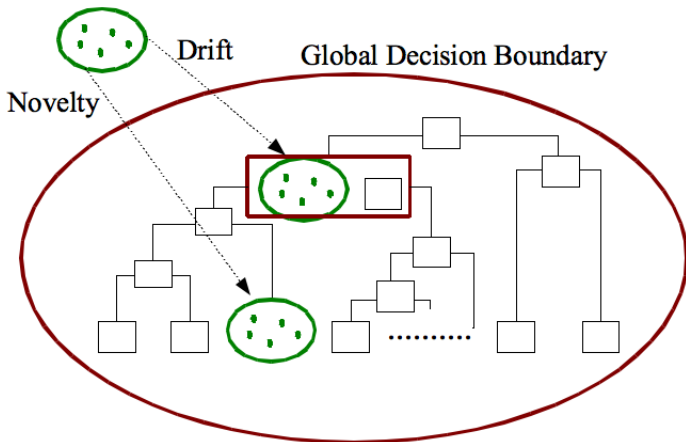

- ① Each individual is assigned to the closest cluster (measuring the distance w.r.t. the cluster medoids)
- ② The entire clustering model is recomputed
- ③ The new instances are considered to be a *candidate* cluster
 - An *evaluation* of it is performed in order to assess its nature

Evaluating the Candidate Cluster: Main Idea 1/2

Evaluating the Candidate Cluster: Main Idea 2/2

Candidate Cluster

Evaluating the Candidate Cluster

- Given the initial clustering model, a *global boundary* is computed for it
 - $\forall C_i \in \text{Model}, \text{decision boundary cluster} = \max_{a_j \in C_i} d(a_j, m_i)$
(or the average)
 - The average of the decision boundary clusters w.r.t. all clusters represent the *decision boundary model or global boundary* d_{overall}
- The decision boundary for the candidate cluster CandCluster is computed $d_{\text{candidate}}$
- if $d_{\text{candidate}} \leq d_{\text{overall}}$ then CandCluster is a *normal* cluster
 - integrate* :
 $\forall a_i \in \text{CandCluster } a_i \rightarrow C_j \text{ s.t. } d(a_i, m_j) = \min_{m_j} d(a_i, m_j)$
- else CandCluster is a **Valid Candidate** for *Concept Drift* or *Novelty Detection*

Evaluating Concept Drift and Novelty Detection

- The *Global Cluster Medoid* is computed
$$\overline{m} := \text{medoid}(\{m_j \mid C_j \in \text{Model}\})$$
- $d_{\max} := \max_{m_j \in \text{Model}} d(\overline{m}, m_j)$
- if $d(\overline{m}, m_{CC}) \leq d_{\max}$ the CandCluster is a *Concept Drift*
 - CandCluster is **Merged** with the most similar cluster $C_j \in \text{Model}$
- if $d(\overline{m}, m_{CC}) \geq d_{\max}$ the CandCluster is a *Novel Concept*
 - CandCluster is **added** to the model (at the level j where the most similar cluster is found)

Experimental Setting

ontology	DL	#concepts	#obj. prop.	#data prop.	#individuals
FSM	<i>SOF(D)</i>	20	10	7	37
S.-W.-M.	<i>ALCCOF(D)</i>	19	9	1	115
TRANSPORTATION	<i>ALC</i>	44	7	0	250
FINANCIAL	<i>ALCIF</i>	60	17	0	652
NTN	<i>SHIF(D)</i>	47	27	8	676

- For each ontology, the *experiments* have been *repeated for varying numbers k* of clusters (**5 through 20**)
- For computing individual distances *all concepts* in the ontology have been used as committee of features
 - this guarantees high redundancy and thus meaningful results
- PELLET reasoner employed for computing the projections

Evaluation Methodology

- Obtained clusters evaluated, per each value of k by the use of the standard metrics
 - **Generalized Dunn's index** $[0, +\infty[$
 - Mean Square error **WSS cohesion index** $[0, +\infty[$
 - within cluster squared sum of distances from medoid
 - **Silhouette index** $[-1, +1]$
- An overall experimentation of **16 repetitions** on a dataset took *from a few minutes to 1.5 hours* on a 2.5GhZ (512Mb RAM) Linux Machine.

Experimental Results 1/3

- Silhouette (most representative index)
 - Close to its max value (1)
- Dunn's + WSS:
 - knees can give a hint of optimal choice for clustering

Experimental Results 2/3

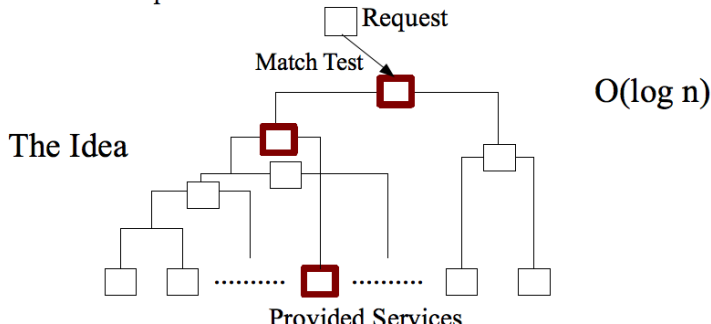

Experimental Results 3/3

Service Discovery: focused aspects

- *Service Discovery* is the task of locating service providers that can satisfy the requester's needs.
- **Service discovery goal:** make service retrieval a (semi-)automatic task.
- **Focused aspects:**
 - *set up methods for describing the service semantics*
 - ① Services are described as *concept instances* of the domain ontology to which they refer [L. Li et al. 2003]
 - ② Services are described as *concept descriptions* by the use of a domain ontology as shared KB [S. Grimm et. al. 2004].
 - *improvement of the effectiveness of the matchmaking process*

A Clustering Method for Improving Service Discovery

Problems to Solve

- ① How to model service descriptions?
- ② How to build the tree-index structure?
- ③ How to represent inner nodes of the tree-index?
- ④ What kind of match test has to be used?

Problems to Solve

- ① **How to model service descriptions?**
- ② How to build the tree-index structure?
- ③ How to represent inner nodes of the tree-index?
- ④ What kind of match test has to be used?

Modelling Service Descriptions

Method proposed by Grimm, Motik, Preist;

- Background knowledge described in Ontology (\mathcal{ALC} ontology in our case)
- Service described as concept expression ($\mathcal{AL}\mathcal{E}(T)$ in our case)
 - **Ex.:** $S_p \equiv \text{Flight} \sqcap \exists \text{from.}\{\text{Cologne}\} \sqcap \exists \text{to.}\{\text{Bari}\}$
- Request described as concept expression
 - **Ex.:**
 $S_r \equiv \text{Flight} \sqcap \exists \text{from.}\{\text{Cologne}, \text{Hahn}, \text{Frankfurt}\} \sqcap \exists \text{to.}\{\text{Bari}\}$

Problems to Solve

- 1 How to model service descriptions?
- 2 **How to build the tree-index structure?**
- 3 How to represent inner nodes of the tree-index?
- 4 What kind of match test has to be used?

The Hierarchical Agglomerative Clustering method

Classical setting:

- Data represented as feature vectors in an n-dimensional space
- Similarity is often measured in terms of geometrical distance
- Output: a dendrogram, namely a tree structure
 - No intentional cluster descriptions are generated

Clustering Service Descriptions

Clustering service descriptions requires:

- to set up a hierarchical agglomerative clustering for Description Logics representations

Issues:

- Which cluster to merge?
 - A similarity measure applicable to complex DL concepts is required
- A conceptual clustering method is needed for producing intensional cluster descriptions
 - Requested a good generalization procedure

The DL-Link Algorithm

[d'Amato et al. @ Service Matchmaking WS at ISWC 2007]

- Modified average-link algorithm
- Adopted GCS-based measure instead of Euclidean measure
- Intentional cluster descriptions generated by means of the GCS of the clusters to merge (Instead of Euclidean average)
- Output: DL-Tree where actual resources are in the leaf nodes, inner nodes are intentional descriptions of the children nodes

Restructuring the DL-Tree

- Since redundant nodes do not add any information
 - If two (or more) children nodes of the DL-Tree have the same intentional description *or*
 - If a parent node has the same description of a child node
 - \Rightarrow a post-processing step is applied to the DL-Tree
- ① *If a child node is equal to another child node* \Rightarrow one of them is deleted and their children nodes are assigned to the remaining node.
- ② *If a child node is equal to a parent node* \Rightarrow the child node is deleted and its children nodes are added as children of its parent node.
- ③ **The result of this flattening process is an n-ary DL-Tree.**

Flattening Post-Processing

Updating the DL-Tree: e.g. a new service occurs

The DL-Tree has not to be entirely re-computed. **Indeed:**

- 1 The similarity value between **Z** and all available services is computed \Rightarrow the most similar service is selected.
- 2 **Z** is added as sibling node of the most similar service while
- 3 the parent node is re-computed as the GCS of the old child nodes plus **Z**.
- 4 In the same way, all the ancestor nodes of the new generated parent node are computed.

Problems to Solve

- 1 How to model service descriptions?
- 2 How to build the tree-index structure?
- 3 How to represent inner nodes of the tree-index?
- 4 **What kind of match test has to be used?**

Service Retrieval Exploiting Clustered Services Descriptions

- Checks for subsumption of an available resource description w.r.t the request
 - Selects only resources able to fully satisfy the request

Data Set for Experiments

- **SWS Discovery Data Set** (handmade and available at <https://www.uni-koblenz.de/FB4/Institutes/IFI/AGStaab/Projects/xmedia/dl-tree.htm>)
 - 93 $\mathcal{AL}\mathcal{E}(T)$ service descriptions referring to
 - an \mathcal{ALC} ontology (bank, post, media, geographical information)
 - developed based on another dataset in order to fit the methodology by Grimm et al

Methodology Evaluation...

SWS Discovery Data set:

- All service descriptions have been clustered by the use of the DL-Link algorithm and a DL-Tree has been obtained

Generated Queries:

- 93 corresponding to the leaf nodes of DL-Tree
- 20 corresponding to some inner nodes
- 116 randomly generated by conjunction /disjunction of primitive and/or defined concepts of the ontology and/or service descriptions.

...Methodology Evaluation

Efficiency of the DL-Tree based method measured by

- Average number of matches in the DL-Tree for finding all resources satisfying the query
- Mean execution time per each query
 - Laptop PowerBook G4 1.67 GHz 1.5 GB RAM

Compared with Linear Matching approach

- Number of matches
- Mean execution time per each query

Evaluation Results

Table: Number of comparison (average and range) and mean execution time for finding all the services satisfying a request w.r.t. the different kinds of requests both in the linear matching and in the DL-Tree based retrieval.

DATA SET	Algorithm	Metrics	Leaf Node	Inner Node	Random Query
SWS Dis.	DL-Tree based	<i>avg.</i>	41.4	23.8	40.3
		<i>range</i>	13 - 56	19 - 27	19 - 79
		<i>avg. exec. time</i>	266.4 ms.	180.2 ms.	483.5 ms.
	Linear	<i>avg.</i>	96	96	96
		<i>avg. exec. time</i>	678.2 ms.	532.5 ms.	1589.3 ms.

Conclusions

- A set of semantic (dis-)similarity measures for DLs has been presented
 - Able to assess (dis-)similarity between complex concepts, individuals and concept/individual
- Experimentally evaluated by embedding them in some inductive-learning algorithms applied to the SW and SWS domains
- Realized an instance based classifier (K-NN and SVM) able to outperform concept retrieval and induce new knowledge
- Realized a set of clustering algorithms for improving the service discovery task and for detecting concept drift and new concepts in an ontology

Future Works...

- Make possible the applicability of the measures to concepts/individuals asserted in different ontologies
- Extend the k-NN-based classifier so that the probability that an individual belongs to one or more concepts are given.
- **For clusters-based discovery process:**
 - Use an heuristic for choosing the best path to follow when two or more nodes satisfy the match at the same level
 - Investigate incremental clustering methods for coping with new available services
 - Use more expressive DL languages for the DL-tree index, e.g. DL-lite instead of *ALC*
 - DL-tree for Other Matches

...Future Works

- **For the detection of new concepts:**
 - Group homogeneous individuals in the candidate cluster and evaluate each group w.r.t. the model
 - Set up the conceptual clustering step as a supervised learning phase with complex DL languages
