## Contents

1. Introduction & Motivation
2. The Reference Representation Language
3. (Dis-)Similarity measures for DLs
4. Applying Measures to Inductive Learning Methods
5. Conclusions and Future Work Proposals
The Semantic Web

- **Semantic Web** is: the new vision of the Web
- **Goal**: make the Web contents *machine-readable* and *processable* besides of human-readable

**How to get** the **SW goal**:
- Adding meta-data to Web resources
- Giving a *shareable and common semantics* to the meta-data by means of *ontologies*
The Role of Ontologies

- An **ontology is** a formal conceptualization of a domain that is shared and reused across domains, tasks and group of people
  - Result of a complex process of knowledge acquisition
- The **ontology role** is to make **semantics explicit**
- Ontological knowledge is generally described by the **Web Ontology Language (OWL)**
  - Supported by **well-founded semantics** of **DLs**
  - together with a series of available automated **reasoning services** allowing to derive logical consequences from an ontology
The main approach used by inference services is *deductive reasoning*.

- logically derived conclusion is of no greater generality than the premises (general axioms).
- Helpful for computing class hierarchy, ontology consistency

Conversely, tasks as *ontology learning, ontology population by assertions, ontology evaluation, ontology mapping* require inferences able to return *higher general conclusions w.r.t. the premises*.

- **Inductive learning methods**, based on *inductive reasoning*, could be effectively used.
Motivations

- Inductive reasoning generates *conclusions* that are of *greater generality* than the premises.
- The starting *premises* are specific, typically *facts or examples*.
- *Conclusions* have *less certainty* than the premises.
- The *goal* is to formulate plausible *general assertions explaining the given facts* and that are able to *predict new facts*. 
Goals

- Apply ML methods, particularly *instance based learning methods*, to the SW and SWS fields for
  - improving reasoning procedures
  - inducing new knowledge not logically derivable
  - improving efficiency and effectiveness of: ontology population, query answering, service discovery and ranking

- Most of the instance-based learning methods require (dis-)similarity measures

  **Problem:** Similarity measures for complex concept descriptions (as those in the ontologies) is a field not deeply investigated [*Borgida et al. 2005*]

  **Solution:** Define new measures for ontological knowledge
  - able to cope with the OWL high expressive power
The Representation Language...

- **DLs** is the *theoretical foundation* of *OWL* language
  - standard de facto for the knowledge representation in the SW
- Knowledge representation by means of Description Logic
  - **$ALC$** logic is *mainly considered* as satisfactory compromise between *complexity* and *expressive power*
The Representation Language

- **Primitive concepts** $N_C = \{C, D, \ldots\}$: subsets of a domain
- **Primitive roles** $N_R = \{R, S, \ldots\}$: binary relations on the domain
- **Interpretation** $\mathcal{I} = (\Delta^\mathcal{I}, \cdot^\mathcal{I})$ where
  - $\Delta^\mathcal{I}$: domain of the interpretation and
  - $\cdot^\mathcal{I}$: interpretation function:

<table>

</tr>
</tbody>
</table>
Knowledge Base & Subsumption

\[ \mathcal{K} = \langle T, A \rangle \]

- **T-box** \( T \) is a set of definitions \( C \equiv D \), meaning \( C^I = D^I \), where \( C \) is the concept name and \( D \) is a description.

- **A-box** \( A \) contains extensional assertions on concepts and roles, e.g. \( C(a) \) and \( R(a, b) \), meaning, resp., that \( a^I \in C^I \) and \( (a^I, b^I) \in R^I \).

**Subsumption**

Given two concept descriptions \( C \) and \( D \), \( C \) subsumes \( D \), denoted by \( C \sqsupseteq D \), iff for every interpretation \( I \), it holds that \( C^I \supseteq D^I \).
**Other Inference Services**

*least common subsumer* is the most specific concept that subsumes a set of considered concepts.

*instance checking* decide whether an individual is an instance of a concept.

*retrieval* find all individuals instance of a concept.

*realization problem* finding the concepts which an individual belongs to, especially the most specific one, if any:

**most specific concept**

Given an A-Box $\mathcal{A}$ and an individual $a$, the *most specific concept* of $a$ w.r.t. $\mathcal{A}$ is the concept $C$, denoted $\text{MSC}_{\mathcal{A}}(a)$, such that $\mathcal{A} \models C(a)$ and $C \sqsubseteq D$, $\forall D$ such that $\mathcal{A} \models D(a)$. 
Why New Measures

- **Already defined similarity/dissimilarity measures cannot be directly applied to ontological knowledge**
  - They define similarity value between *atomic concepts*
  - They are defined for *representation less expressive* than ontology representation
  - They *cannot exploit all the expressiveness* of the *ontological representation*
  - **There are no measure for assessing similarity between individuals**

- **Defining new measures that are really semantic is necessary**
Similarity Measure between Concepts: Needs

- Necessity to have a measure really based on Semantics
- Considering [Tversky’77]:
  - common features tend to increase the perceived similarity of two concepts
  - feature differences tend to diminish perceived similarity
  - feature commonalities increase perceived similarity more than feature differences can diminish it
- The proposed similarity measure is:
Similarity Measure between Concepts

**Definition [d’Amato et al. @ CILC 2005]:** Let \( \mathcal{L} \) be the set of all concepts in \( \mathcal{ALC} \) and let \( \mathcal{A} \) be an A-Box with canonical interpretation \( \mathcal{I} \). The *Semantic Similarity Measure* \( s \) is a function

\[
s : \mathcal{L} \times \mathcal{L} \mapsto [0, 1]
\]

defined as follows:

\[
s(C, D) = \frac{|\mathcal{I}\cap|}{|\mathcal{I}\cap| + |\mathcal{I}\cap| - |\mathcal{I}|} \cdot \max\left(\frac{|\mathcal{I}\cap|}{|\mathcal{I}\cap|}, \frac{|\mathcal{I}\cap|}{|\mathcal{I}\cap|}\right)
\]

where \( I = C \cap D \) and \( (\cdot)^I \) computes the concept extension wrt the interpretation \( \mathcal{I} \).
Similarity Measure: Meaning

- If $C \equiv D$ ($C \subseteq D$ and $D \subseteq C$) then $s(C, D) = 1$, i.e. the maximum value of the similarity is assigned.
- If $C \sqcap D = \bot$ then $s(C, D) = 0$, i.e. the minimum similarity value is assigned because concepts are totally different.
- Otherwise $s(C, D) \in ]0, 1[$. The similarity value is proportional to the overlapping amount of the concept extensions reduced by a quantity representing how the two concepts are near to the overlap. This means considering similarity not as an absolute value but as weighted w.r.t. a degree of non-similarity.
Similarity Measure between Individuals

Let \( c \) and \( d \) two individuals in a given A-Box. We can consider \( C^* = MSC^*(c) \) and \( D^* = MSC^*(d) \):

\[
s(c, d) := s(C^*, D^*) = s(MSC^*(c), MSC^*(d))
\]

Analogously:

\[
\forall a : s(c, D) := s(MSC^*(c), D)
\]
Discussion

- The presented function is a similarity measure
  1. $f(a, b) \geq 0 \ \forall a, b \in E \ (positive \ definiteness)$
  2. $f(a, b) = f(b, a) \ \forall a, b \in E \ (symmetry)$
  3. $\forall a, b \in E : f(a, b) \leq f(a, a)$

- Computational Complexity
  - Similarity between concepts: $Compl(s) = 3 \cdot Compl(IC)$
  - Similarity individual-concept:
    $Compl(s) = Compl(MSC^*) + 3 \cdot Compl(IC)$
  - Similarity between individuals:
    $Compl(s) = 2 \cdot Compl(MSC^*) + 3 \cdot Compl(IC)$
Similarity Measure: Conclusions...

- $s$ is a *Semantic* Similarity measure
  - It uses only *semantic inference* (Instance Checking) for determining similarity values
  - It does *not make use of the syntactic structure* of the concept descriptions
  - It does *not add complexity besides of* the complexity of *used inference operator* ($IChk$ that is PSPACE in $\mathcal{ALC}$)

- Dissimilarity Measure is defined using the set theory and reasoning operators
  - It uses a *numerical approach but it is applied to symbolic representations*
Similarity Measure: Conclusions

- Experimental evaluations demonstrate that $s$ works satisfying when it is applied between concepts.
- $s$ applied to individuals is often zero even in case of similar individuals.
  - The $MSC^*$ is so specific that often covers only the considered individual and not similar individuals.
- The new idea is to measure the similarity (dissimilarity) of the subconcepts that build the $MSC^*$ concepts in order to find their similarity (dissimilarity).
  - Intuition: Concepts defined by almost the same sub-concepts will be probably similar.
A Semantic Similarity Measure for \( \mathcal{ALC} \)
A Dissimilarity Measure for \( \mathcal{ALC} \)
Weighted Dissimilarity Measure for \( \mathcal{ALC} \)
A Dissimilarity Measure for \( \mathcal{ALC} \) using Information Content
A Similarity Measure for \( \mathcal{ALN} \)
A Relational Kernel Function for \( \mathcal{ALC} \)
A Semantic Semi-Distance Measure for Any DLs

**\( \mathcal{ALC} \) Normal Form**

\( D \) is in \( \mathcal{ALC} \) normal form iff \( D \equiv \bot \) or \( D \equiv \top \) or if
\( D = D_1 \sqcup \cdots \sqcup D_n \ (\forall i = 1, \ldots, n, \ D_i \neq \bot) \) with

\[
D_i = \bigcap_{A \in \text{prim}(D_i)} A \sqcap \bigcap_{R \in N_R} \left[ \forall R.\text{val}_R(D_i) \sqcap \bigcap_{E \in \text{ex}_R(D_i)} \exists R. E \right]
\]

where:

- \( \text{prim}(C) \) set of all (negated) atoms occurring at \( C \)'s top-level
- \( \text{val}_R(C) \) conjunction \( C_1 \sqcap \cdots \sqcap C_n \) in the value restriction on \( R \), if any (o.w. \( \text{val}_R(C) = \top \));
- \( \text{ex}_R(C) \) set of concepts in the value restriction of the role \( R \)

For any \( R \), every sub-description in \( \text{ex}_R(D_i) \) and \( \text{val}_R(D_i) \) is in normal form.
Overlap Function

Definition [d’Amato et al. @ KCAP 2005 Workshop]:

\[ \mathcal{L} = \mathcal{ALC}/_\equiv \text{ the set of all concepts in } \mathcal{ALC} \text{ normal form} \]
\[ \mathcal{I} \text{ canonical interpretation of A-Box } \mathcal{A} \]

\[ f : \mathcal{L} \times \mathcal{L} \mapsto R^+ \text{ defined } \forall C = \bigsqcup_{i=1}^{n} C_i \text{ and } D = \bigsqcup_{j=1}^{m} D_j \text{ in } \mathcal{L}/_\equiv \]

\[ f(C, D) := f_{\sqcup}(C, D) = \begin{cases} 
\infty & \text{if } C \equiv D \\
0 & \text{if } C \sqcap D \equiv \bot \\
\max_{i = 1, \ldots, n} \text{ } f_{\sqcap}(C_i, D_j) & \text{o.w.} \\
\end{cases} \]

\[ f_{\sqcap}(C_i, D_j) := f_P(\text{prim}(C_i), \text{prim}(D_j)) + f_\forall(C_i, D_j) + f_\exists(C_i, D_j) \]
Overlap Function / II

\[
f_P(\text{prim}(C_i), \text{prim}(D_j)) := \frac{|(\text{prim}(C_i))^I \cup (\text{prim}(D_j))^I|}{|((\text{prim}(C_i))^I \cup (\text{prim}(D_j))^I) \setminus ((\text{prim}(C_i))^I \cap (\text{prim}(D_j))^I)|}
\]

\[
f_P(\text{prim}(C_i), \text{prim}(D_j)) := \infty \text{ if } (\text{prim}(C_i))^I = (\text{prim}(D_j))^I
\]

\[
f_V(C_i, D_j) := \sum_{R \in N_R} f_{\sqcup}(\text{val}_R(C_i), \text{val}_R(D_j))
\]

\[
f_E(C_i, D_j) := \sum_{R \in N_R} \sum_{k=1}^{N} \max_{p=1, \ldots, M} f_{\sqcup}(C_i^k, D_j^p)
\]

where \( C_i^k \in \text{ex}_R(C_i) \) and \( D_j^p \in \text{ex}_R(D_j) \) and wlog. \( N = |\text{ex}_R(C_i)| \geq |\text{ex}_R(D_j)| = M \), otherwise exchange \( N \) with \( M \).
Dissimilarity Measure

The dissimilarity measure \( d \) is a function \( d : \mathcal{L} \times \mathcal{L} \rightarrow [0, 1] \) such that, for all \( C = \bigcup_{i=1}^{n} C_i \) and \( D = \bigcup_{j=1}^{m} D_j \) concept descriptions in \( \mathcal{ALC} \) normal form:

\[
\begin{align*}
0 & \quad f(C, D) = \infty \\
1 & \quad f(C, D) = 0 \\
\frac{1}{f(C,D)} & \quad \text{otherwise}
\end{align*}
\]

where \( f \) is the function overlapping
Discussion

- If $C \equiv D$ (namely $C \sqsubseteq D$ or $D \sqsubseteq C$) (semantic equivalence) $d(C, D) = 0$, rather $d$ assigns the minimum value.
- If $C \sqcap D \equiv \bot$ then $d(C, D) = 1$, rather $d$ assigns the maximum value because concepts involved are totally different.
- Otherwise $d(C, D) \in ]0, 1[$ rather *dissimilarity is inversely proportional to the quantity of concept overlap*, measured considering the entire definitions and their subconcepts.
Dissimilarity Measure: Conclusions

- Experimental evaluations demonstrate that $d$ works satisfying both for concepts and individuals.

- However, for complex descriptions (such as $\text{MSC}^*$), deeply nested subconcepts could increase the dissimilarity value.

- New idea: differentiate the weight of the subconcepts wrt their levels in the descriptions for determining the final dissimilarity value.

- Solve the problem: how differences in concept structure might impact concept (dis-)similarity? i.e. considering the series $\text{dist}(B, B \sqcap A)$, $\text{dist}(B, B \sqcap \forall R.A)$, $\text{dist}(B, B \sqcap \forall R.\forall R.A)$ this should become smaller since more deeply nested restrictions ought to represent smaller differences.” [Borgida et al. 2005]
The weighted Dissimilarity Measure

Overlap Function Definition [d’Amato et al. @ SWAP 2005]:
\[ L = \mathcal{ALC}/\equiv \] the set of all concepts in \( \mathcal{ALC} \) normal form
\[ I \] canonical interpretation of A-Box \( A \)

\[ f : L \times L \mapsto R^+ \] defined \( \forall C = \bigsqcup_{i=1}^{n} C_i \) and \( D = \bigsqcup_{j=1}^{m} D_j \) in \( L\equiv \)

\[ f(C, D) := f\sqcup(C, D) = \begin{cases} 
|\Delta| & C \equiv D \\
0 & C \sqcap D \equiv \bot \\
1 + \lambda \cdot \max_{i=1,\ldots,n} f\sqcap(C_i, D_j) & \text{o.w.}
\end{cases} \]

\[ f\sqcap(C_i, D_j) := f_P(\text{prim}(C_i), \text{prim}(D_j)) + f\forall(C_i, D_j) + f\exists(C_i, D_j) \]
Looking toward Information Content: Motivation

- The use of Information Content is presented as the most effective way for measuring complex concept descriptions [Borgida et al. 2005]
- The necessity of considering concepts in normal form for computing their (dis-)similarity is argued [Borgida et al. 2005]
  - confirmation of the used approach in the previous measure
- A dissimilarity measure for complex descriptions grounded on IC has been defined
  - ALC concepts in normal form
  - based on the structure and semantics of the concepts.
  - elicits the underlying semantics, by querying the KB for assessing the IC of concept descriptions w.r.t. the KB
  - extension for considering individuals
Information Content: Definition

- A measure of concept (dis)similarity can be derived from the notion of Information Content (IC).
- IC depends on the probability of an individual to belong to a certain concept.
  - $IC(C) = - \log pr(C)$
- In order to approximate the probability for a concept $C$, it is possible to recur to its extension wrt the considered ABox.
  - $pr(C) = |C^I|/|\Delta^I|$ 
- A function for measuring the IC variation between concepts is defined
Function Definition /I

[d’Amato et al. @ SAC 2006] \( \mathcal{L} = \mathcal{ALC}/\equiv \) the set of all concepts in \( \mathcal{ALC} \) normal form

\( \mathcal{I} \) canonical interpretation of A-Box \( \mathcal{A} \)

\[ f : \mathcal{L} \times \mathcal{L} \mapsto R^+ \] defined \( \forall C = \bigsqcup_{i=1}^{n} C_i \) and \( D = \bigsqcup_{j=1}^{m} D_j \) in \( \mathcal{L}/\equiv \)

\[ f(C, D) := f_{\sqcup}(C, D) = \begin{cases} 0 & C \equiv D \\ \infty & C \sqcap D \equiv \bot \\ \max_{i = 1, \ldots, n} f_{\sqcap}(C_i, D_j) & \text{o.w.} \end{cases} \]

\[ f_{\sqcap}(C_i, D_j) := f_P(\text{prim}(C_i), \text{prim}(D_j)) + f_{\forall}(C_i, D_j) + f_{\exists}(C_i, D_j) \]
Function Definition / II

\[ f_P(\text{prim}(C_i), \text{prim}(D_j)) := \begin{cases} 
\infty & \text{if } \text{prim}(C_i) \sqcap \text{prim}(D_j) \equiv \bot \\
\frac{IC(\text{prim}(C_i) \sqcap \text{prim}(D_j)) + 1}{IC(LCS(\text{prim}(C_i), \text{prim}(D_j))) + 1} & \text{o.w.}
\end{cases} \]

\[ f_\forall(C_i, D_j) := \sum_{R \in N_R} f_{\sqcup}(\text{val}_R(C_i), \text{val}_R(D_j)) \]

\[ f_\exists(C_i, D_j) := \sum_{R \in N_R} \sum_{k=1}^{N} \max_{p=1, \ldots, M} f_{\sqcup}(C^k_i, D^p_j) \]

where \( C^k_i \in \text{ex}_R(C_i) \) and \( D^p_j \in \text{ex}_R(D_j) \) and wlog. \( N = |\text{ex}_R(C_i)| \geq |\text{ex}_R(D_j)| = M \), otherwise exchange \( N \) with \( M \).
Dissimilarity Measure: Definition

The *dissimilarity measure* \( d \) is a function \( d : \mathcal{L} \times \mathcal{L} \mapsto [0, 1] \) such that, for all \( C = \bigcup_{i=1}^{n} C_i \) and \( D = \bigcup_{j=1}^{m} D_j \) concept descriptions in ALC normal form:

\[
d(C, D) := \begin{cases} 
0 & f(C, D) = 0 \\
1 & f(C, D) = \infty \\
1 - \frac{1}{f(C, D)} & \text{otherwise}
\end{cases}
\]

where \( f \) is the function defined previously.
Discussion

- \( d(C, D) = 0 \) iff IC=0 iff \( C \equiv D \) (semantic equivalence) rather \( d \) assigns the minimum value
- \( d(C, D) = 1 \) iff IC \( \rightarrow \infty \) iff \( C \sqcap D \equiv \bot \), rather \( d \) assigns the maximum value because concepts involved are totally different
- Otherwise \( d(C, D) \in ]0, 1[ \) rather \( d \) tends to 0 if IC tends to 0; \( d \) tends to 1 if IC tends to infinity
**ALN Normal Form**

C is in **ALN** normal form iff $C \equiv \bot$ or $C \equiv \top$ or if

$$C = \prod_{P \in \text{prim}(C)} P \sqcap \prod_{R \in N_R} (\forall R. C_R \sqcap \geq n.R \sqcap \leq m.R)$$

where:

- $C_R = \text{val}_R(C)$, $n = \min_R(C)$ and $m = \max_R(C)$

**prim(C)** set of all (negated) atoms occurring at $C$'s top-level

**val}_R(C)** conjunction $C_1 \sqcap \cdots \sqcap C_n$ in the value restriction on $R$, if any (o.w. $\text{val}_R(C) = \top$);

- $\min_R(C) = \max\{n \in N \mid C \sqsubseteq (\geq n.R)\}$ (always finite number);

- $\max_R(C) = \min\{n \in N \mid C \sqsubseteq (\leq n.R)\}$ (if unlimited $\max_R(C) = \infty$)
Measure Definition / 1

[Fanizzi et. al @ CILC 2006] $\mathcal{L} = \mathcal{ALN} / \equiv$ the set of all concepts in $\mathcal{ALN}$ normal form $\mathcal{I}$ canonical interpretation of $\mathcal{A}$

A-Box $s : \mathcal{L} \times \mathcal{L} \mapsto [0, 1]$ defined $\forall C, D \in \mathcal{L}$:

\[
s(C, D) := \lambda [s_P(\text{prim}(C), \text{prim}(D)) + \frac{1}{|N_R|} \sum_{R \in N_R} s(\text{val}_R(C), \text{val}_R(D)) + \frac{1}{|N_R|} \cdot \sum_{R \in N_R} s_N((\min_R(C), \max_R(C)), (\min_R(D), \max_R(D)))]
\]

where $\lambda \in ]0, 1]$ (let $\lambda = 1/3$),
Measure Definition / II

$$s_P(\text{prim}(C), \text{prim}(D)) := \frac{\left| \bigcap_{P_C \in \text{prim}(C)} P_C^T \bigcap \bigcap_{Q_D \in \text{prim}(D)} Q_D^T \right|}{\left| \bigcap_{P_C \in \text{prim}(C)} P_C^T \bigcup \bigcap_{Q_D \in \text{prim}(D)} Q_D^T \right|}$$

$$s_N((m_C, M_C), (m_D, M_D)) := \frac{\min(M_C, M_D) - \max(m_C, m_D) + 1}{\max(M_C, M_D) - \min(m_C, m_D) + 1}$$

$$s_N((m_C, M_C), (m_D, M_D)) := 0 \text{ if } \min(M_C, M_D) > \max(m_C, m_D)$$

C. d'Amato
Similarity-based Learning Methods for the SW
Relational Kernel Function: Motivation

- Kernel functions jointly with a kernel method.
- Advantages: 1) efficiency; 2) the learning algorithm and the kernel are almost completely independent.
  - An efficient algorithm for attribute-value instance spaces can be converted into one suitable for structured spaces by merely replacing the kernel function.
- A kernel function for ALC normal form concept descriptions has been defined.
  - Based both on the syntactic structure (exploiting the convolution kernel [Haussler 1999] and on the semantics, derived from the ABox.
Kernel Definition/I

[Fanizzi et al. @ ISMIS 2006] Given the space $X$ of $\mathcal{ALC}$ normal form concept descriptions, $D_1 = \bigcup_{i=1}^{n} C_i^1$ and $D_2 = \bigcup_{j=1}^{m} C_j^2$ in $X$, and an interpretation $\mathcal{I}$, the $\mathcal{ALC}$ kernel based on $\mathcal{I}$ is the function $k_{\mathcal{I}} : X \times X \mapsto \mathbb{R}$ inductively defined as follows.

**disjunctive descriptions:**

$$k_{\mathcal{I}}(D_1, D_2) = \lambda \sum_{i=1}^{n} \sum_{j=1}^{m} k_{\mathcal{I}}(C_i^1, C_j^2) \quad \text{with } \lambda \in ]0, 1]$$

**conjunctive descriptions:**

$$k_{\mathcal{I}}(C^1, C^2) = \prod_{P_1 \in \text{prim}(C^1)} k_{\mathcal{I}}(P_1, P_2) \cdot \prod_{R \in N_R} k_{\mathcal{I}}(\text{val}_R(C^1), \text{val}_R(C^2)) \cdot \prod_{R \in N_R} \sum_{C_i^1 \in \text{ex}_R(C^1)} \sum_{C_j^2 \in \text{ex}_R(C^2)} k_{\mathcal{I}}(C_i^1, C_j^2)$$
Kernel Definition/II

primitive concepts:

$$k_{\mathcal{I}}(P_1, P_2) = \frac{k_{\text{set}}(P_1^\mathcal{I}, P_2^\mathcal{I})}{|\Delta^\mathcal{I}|} = \frac{|P_1^\mathcal{I} \cap P_2^\mathcal{I}|}{|\Delta^\mathcal{I}|}$$

where $k_{\text{set}}$ is the kernel for set structures [Gaertner 2004]. This case includes also the negation of primitive concepts using set difference: $(-P)^\mathcal{I} = \Delta^\mathcal{I} \setminus P^\mathcal{I}$
Kernel function: Discussion

- The kernel function can be extended to the case of individuals/concept
- The kernel is *valid*
  - The function is symmetric
  - The function is closed under multiplication and sum of valid kernel (kernel set).
- Being the kernel valid, and *induced distance measure* (metric) can be obtained [Haussler 1999]

\[
d_\mathcal{I}(C, D) = \sqrt{k_\mathcal{I}(C, C) - 2k_\mathcal{I}(C, D) + k_\mathcal{I}(D, D)}
\]
Semi-Distance Measure: Motivations

- Most of the presented measures are grounded on concept structures ⇒ hardly scalable w.r.t. most expressive DLs
- **IDEA**: on a semantic level, similar individuals should behave similarly w.r.t. the same concepts
- Following HDD [Sebag 1997]: individuals can be compared on the grounds of their behavior w.r.t. a given set of hypotheses $F = \{F_1, F_2, \ldots, F_m\}$, that is a collection of (primitive or defined) concept descriptions
  - $F$ stands as a group of discriminating features expressed in the considered language
- As such, the new measure totally depends on semantic aspects of the individuals in the KB
Semantic Semi-Distance Measure: Definition

[Fanizzi et al. @ DL 2007] Let \( \mathcal{K} = \langle \mathcal{T}, \mathcal{A} \rangle \) be a KB and let \( \text{Ind}(\mathcal{A}) \) be the set of the individuals in \( \mathcal{A} \). Given sets of concept descriptions \( \mathcal{F} = \{F_1, F_2, \ldots, F_m\} \) in \( \mathcal{T} \), a family of semi-distance functions \( d_p^F : \text{Ind}(\mathcal{A}) \times \text{Ind}(\mathcal{A}) \mapsto \mathbb{R} \) is defined as follows:

\[
\forall a, b \in \text{Ind}(\mathcal{A}) \quad d_p^F(a, b) := \frac{1}{m} \left[ \sum_{i=1}^{m} | \pi_i(a) - \pi_i(b) |^p \right]^{1/p}
\]

where \( p > 0 \) and \( \forall i \in \{1, \ldots, m\} \) the projection function \( \pi_i \) is defined by:

\[
\forall a \in \text{Ind}(\mathcal{A}) \quad \pi_i(a) = \begin{cases} 
1 & F_i(x) \in \mathcal{A} \quad (\mathcal{K} \models F_i(x)) \\
0 & \neg F_i(x) \in \mathcal{A} \quad (\mathcal{K} \models \neg F_i(x)) \\
\frac{1}{2} & \text{otherwise}
\end{cases}
\]
Semi-Distance Measure: Discussion

- More similar the considered individuals are, more similar the project function values are ⇒ $d_p^F ≃ 0$
- More different the considered individuals are, more different the projection values are ⇒ the value of $d_p^F$ will increase

The measure complexity mainly depends from the complexity of the Instance Checking operator for the chosen DL

- $\text{Compl}(d_p^F) = |F| \cdot 2 \cdot \text{Compl}(\text{IChk})$

- Optimal discriminating feature set could be learned
Goals for using Inductive Learning Methods in the SW

Instance-base classifier for

- Semi-automatize the A-Box population task
- Induce new knowledge not logically derivable
- Improve concept retrieval and query answering inference service

*Realized algorithms*

- Relational K-NN
- Relational kernel embedded in a SVM

Unsupervised learning methods for

- Improve service discovery task
- Exploiting (dis-)similarity measures for improving the ranking of the retrieved services
Classical K-NN algorithm...

classes: $a, b$; $d$ $k = 5$;

Test example
...Classical K-NN algorithm...

$C(x_q) = a$

classes: $a, b$; $d$ $k = 5$;
Classical K-NN algorithm

- Generally applied to feature vector representation
- In classification phase it is assumed that each training and test example belong to a single class, so classes are considered to be disjoint
- An implicit *Closed World Assumption* is made
Difficulties in applying K-NN to Ontological Knowledge

To apply K-NN for classifying individual asserted in an ontological knowledge base

1. It has to find a way for applying K-NN to a most complex and expressive knowledge representation

2. It is not possible to assume disjointness of classes. Individuals in an ontology can belong to more than one class (concept).

3. The classification process has to cope with the *Open World Assumption* charactering Semantic Web area
Choices for applying K-NN to Ontological Knowledge

1. To have similarity and dissimilarity measures applicable to ontological knowledge allows applying K-NN to this kind of knowledge representation.

2. A new classification procedure is adopted, decomposing the multi-class classification problem into smaller binary classification problems (one per target concept).
   - For each individual to classify w.r.t each class (concept), classification returns \{-1, +1\}

3. A third value 0 representing unknown information is added in the classification results \{-1,0,+1\}

4. Hence a majority voting criterion is applied.
Realized K-NN Algorithm...

[d’Amato et al. @ URSW Workshop at ISWC 2006]

- **Main Idea:** similar individuals, by analogy, should likely belong to similar concepts
  - for every ontology, all individuals are classified to be instances of one or more concepts of the considered ontology
- For each individual in the ontology MSC is computed
- MSC list represents the set of training examples
Realized K-NN Algorithm

Each example is classified applying the k-NN method for DLs, adopting the leave-one-out cross validation procedure.

\[
\hat{h}_j(x_q) := \arg\max_{v \in V} \sum_{i=1}^{k} \omega_i \cdot \delta(v, h_j(x_i)) \quad \forall j \in \{1, \ldots, s\}
\]

where

\[
h_j(x) = \begin{cases} 
+1 & C_j(x) \in A \\
0 & C_j(x) \notin A \\
-1 & \neg C_j(x) \in A 
\end{cases}
\]

Measures for Evaluating Experiments

- **Performance evaluated** by *comparing the procedure responses to those returned by a standard reasoner* (Pellet)
- **Predictive Accuracy:** measures the number of correctly classified individuals w.r.t. overall number of individuals.
- **Omission Error Rate:** measures the amount of unlabelled individuals $C(x_q) = 0$ with respect to a certain concept $C_j$ while they are instances of $C_j$ in the KB.
- **Commission Error Rate:** measures the amount of individuals labelled as instances of the negation of the target concept $C_j$, while they belong to $C_j$ or vice-versa.
- **Induction Rate:** measures the amount of individuals that were found to belong to a concept or its negation, while this information is not derivable from the KB.
### Experimentation Evaluation

Experimentation: Discussion...

- For every ontology, the *commission error is null*; the classifier never makes critical mistakes.

- **FSM Ontology**: the classifier always assigns individuals to the correct concepts; *it is never capable to induce new knowledge*.
  - Because individuals are all instances of a single concept and are involved in a few roles, so MSCs are very similar and so the amount of information they convey is very low.
...Experimentation: Discussion...

SURFACE-WATER-MODEL and FINANCIAL Ontology

- The classifier always assigns individuals to the correct concepts
  - Because most of individuals are instances of a single concept
- Induction rate is not null so *new knowledge is induced*. This is mainly due to
  - some *concepts* that are declared to be *mutually disjoint*
  - some *individuals* are *involved in relations*
...Experimentation: Discussion

**FAMILY Ontology**

- Predictive Accuracy is not so high and Omission Error not null
  - Because instances are more irregularly spread over the classes, so computed MSCs are often very different provoking sometimes incorrect classifications (weakness on K-NN algorithm)
- No Commission Error (but only omission error)
- The *Classifier* is able of *induce new knowledge* that is *not derivable*
Comparing the Measures

- The measure based on IC **poorly classifies concepts** that have *less information* in the ontology.
  - *The measure based on IC is less able*, w.r.t. the measure based on overlap, *to classify concepts* correctly, when they have *few information* (instance and object properties involved);
- **Comparable behavior** when *enough information* is available
- **Inducted knowledge can be used for**
  - *semi-automatize ABox population*
  - *improving concept retrieval*
Experiments: Querying the KB exploiting relational K-NN

Setting

- **15** queries randomly generated by conjunctions/disjunctions of primitive or defined concepts of each ontology.
- **Classification of all individuals in each ontology w.r.t the query concept**
- Performance evaluated by comparing the procedure responses to those returned by a standard reasoner (Pellet) employed as a baseline.
- The *Semi-distance measure* has been used
  - *All concepts in ontology have been employed as feature set* $F$

</tbody>
</table>
Experimentation: Discussion

- Very low commission error: almost never the classifier makes critical mistakes
- Very high match rate 95% (more than the previous measures 80%) ⇒ Highly comparable with the reasoner
- Very low induction rate ⇒ Less able (w.r.t. previous measures) to induce new knowledge
- Lower match rate for Financial ontology as data are not enough sparse
- The usage of all concepts for the set $F$ made the measure accurate, which is the reason why the procedure resulted conservative as regards inducing new assertions.
Testing the Effect of the Variation of $F$ on the Measure

- **Expected result**: with an increasing number of considered hypotheses for $F$, the accuracy of the measure would increase accordingly.

- **Considered ontology**: *Financial* as it is the most populated

- Experiment repeated with an increasing percentage of concepts randomly selected for $F$ from the ontology.

- Results confirm the hypothesis

- **Similar results for the other ontologies**

SVM and Relational Kernel Function for the SW

- A SMV is a classifier that, by means of kernel function implicitly, maps the training data into a higher dimensional feature space where they can be classified using a linear classifier
  - A SVM from the LIBSVM library has been considered
- **Learning Problem**: Given an ontology, classify all its individuals w.r.t. all concepts in the ontology [Fanizzi et al. @ KES 2007]
- **Problems to solve**: 1) Implicit CWA; 2) Assumption of class disjointness
- **Solutions**: Decomposing the classification problem is a set of ternary classification problems \{+1, 0, −1\}, for each concept of the ontology

</table>
Experiments: Discussion

- High matching rate
- Induction Rate not null $\Rightarrow$ new knowledge is induced
- For every ontology, the commission error is quite low $\Rightarrow$ the classifier does not make critical mistakes
  - Not null for UNIVERSITY and FSM ontologies $\Rightarrow$ They have the lowest number of individuals
  - There is not enough information for separating the feature space producing a correct classification
- In general, the match rate increases with the increase of the number of individuals in the ontology
  - Consequently, the commission error rate decreases
- Similar results by using the classifier for querying the KB
Why the Attention to Modeling Service Descriptions

- WS Technology has allowed uniform access via Web standards to software components residing on various platforms and written in different programming languages
- *WS major limitation:* their retrieval and composition still require manual effort
- *Solution:* augment WS with a semantic description of their functionality ⇒ *SWS*
- *Choice:* DLs as representation language, *because:*
  - DLs are endowed by a formal semantics ⇒ guarantee expressive service descriptions and precise semantics definition
  - DLs are the theoretical foundation of OWL ⇒ ensure compatibility with existing ontology standards
  - *Service discovery* can be performed exploiting standard and non-standard DL inferences
DLs-based Service Descriptions

[Grimm et al. 2004] A service description is expressed by a set of DL-axioms $D = \{S, \phi_1, \phi_2, ..., \phi_n\}$, where the axioms $\phi_i$ impose restrictions on an atomic concept $S$, which represents the service to be performed

$$D_r = \{ S_r \equiv \text{Company} \sqcap \exists \text{payment.EPayment} \sqcap \exists \text{to.\{bari\}} \sqcap$$
$$\sqcap \exists \text{from.\{cologne,hahn\}} \sqcap \leq 1 \text{ hasAlliance} \sqcap$$
$$\sqcap \forall \text{hasFidelityCard.\{milesAndMore\}}; \{\text{cologne,hahn}\} \sqsubseteq \exists \text{from}^- . S_r \}$$

$$KB = \{\text{cologne:Germany, hahn:Germany, bari:Italy, milesAndMore:Card}\}$$
Introducing Constraint Hardness

- [d’Amato et al. @ Sem4WS Workshop at BPM 2006] In real scenarios a service request is characterized by some needs that must be satisfied and others that may be satisfied.
- HC represent necessary and sufficient conditions for selecting requested service instances.
- SC represent only necessary conditions.

**Definition**

Let $D_r^{HC} = \{S_r^{HC}, \sigma_1^{HC}, ..., \sigma_n^{HC}\}$ be the set of HC for a requested service description $D_r$ and let $D_r^{SC} = \{S_r^{SC}, \sigma_1^{SC}, ..., \sigma_m^{SC}\}$ be the set of SC for $D_r$. The complete description of $D_r$ is given by $D_r = \{S_r \equiv S_r^{HC} \sqcup S_r^{SC}, \sigma_1^{HC}, ..., \sigma_n^{HC}, \sigma_1^{SC}, ..., \sigma_m^{SC}\}$. 

C. d’Amato | Similarity-based Learning Methods for the SW
Modelling Service Descriptions: Example

\[ D_r = \{ \quad S_r \equiv \text{Flight} \sqcap \exists \text{from.} \{\text{Cologne, Hahn, Frankfurt}\} \sqcap \exists \text{to.} \{\text{Bari}\} \sqcap \exists \text{hasFidelityCard.} \{\text{MilesAndMore}\}; \quad \{\text{Cologne, Hahn, Frankfurt}\} \sqsubseteq \exists \text{from}^{-}.S_r; \quad \{\text{Bari}\} \sqsubseteq \exists \text{to}^{-}.S_r \quad \} \]

where

\[ HC_r = \{ \quad \text{Flight} \sqcap \exists \text{to.} \{\text{Bari}\} \sqcap \exists \text{from.} \{\text{Cologne, Hahn, Frankfurt}\}; \quad \{\text{Cologne, Hahn, Frankfurt}\} \sqsubseteq \exists \text{from}^{-}.S_r; \quad \{\text{Bari}\} \sqsubseteq \exists \text{to}^{-}.S_r \quad \} \]

\[ SC_r = \{ \quad \text{Flight} \sqcap \forall \text{hasFidelityCard.} \{\text{MilesAndMore}\} \quad \} \]

\[ KB = \{ \quad \text{Cologne,Hahn, Frankfurt: Germany, Bari: Italy,} \quad \text{MilesAndMore: Card} \} \]
Discovery and Matching Services

- **Service Discovery** is the task of locating service providers that can satisfy the requesters needs.
- Discovery is performed by *matching a requested service description to the service descriptions of potential providers*.
- The matching process (w.r.t. a KB) is expressed as a boolean function \( \text{match}(KB, D_r, D_p) \) which specifies how to apply DL inferences to perform the matching.
The Matching Process

Let \( D_r = \{ S_r, \sigma_1, \ldots, \sigma_n \} \) be a requested service description and \( D_p = \{ S_p, \sigma_1, \ldots, \sigma_m \} \) a provided service description.

- **Satisfiability of Concept Conjunction** [Trastour 2001]
  \[
  KB \cup D_r \cup D_p \cup \{ \exists x : S_r(x) \land S_p(x) \} \text{ is consistent} \iff \nsim \\
  \iff KB \cup D_r \cup D_p \cup \{ i : S_r \cap S_p \} \text{ is satisfiable}
  \]

- **Entailment of Concept Subsumption** [Paolucci 2002]
  \[
  KB \cup D_r \cup D_p \cup \{ \exists x : S_r(x) \land S_p(x) \} \text{ is consistent} \iff \nsim \\
  \iff KB \cup D_r \cup D_p \cup \{ i : S_r \cap S_p \} \text{ is satisfiable}
  \]

- **Entailment of Concept Non-Disjointness** [Grimm 2004]
  \[
  KB \cup D_r \cup D_p \models \exists x : S_r(x) \land S_p(x) \iff \nsim \\

Similarity-based Learning Methods for the SW
Problems to Solve

- A *hierarchical agglomerative clustering method* is necessary in order to have a dendrogram (tree) as output of the clustering process
  - A *(dis-)similarity measure* applicable to *complex DL concept descriptions* is necessary for grouping elements
- A *conceptual clustering method* is necessary in order to generate *intensional cluster descriptions* of inner nodes
  - Availability of a *"good" generalization procedure*
Building intensional cluster descriptions

Possible generalization procedures

- **LCS-ALC** ⇒ it could be too much specific (over-fitting)
- Approximating every **ALC** concept descriptions to **ALE** description [Brandt et al. 2002] ⇒ computing the **LCS-ALE**
The hierarchical agglomerative clustering approach

Classical setting:
- Data are represented as feature vectors in an n-dimensional space
- Similarity is often measured in terms of geometrical distance
The hierarchical agglomerative clustering approach

Classical setting:
- Data are represented as feature vectors in an n-dimensional space
- Similarity is often measured in terms of geometrical distance
The hierarchical agglomerative clustering approach

Classical setting:
- Data are represented as feature vectors in an n-dimensional space.
- Similarity is often measured in terms of geometrical distance.

- Similarity is often measured in terms of geometrical distance
Realized clustering algorithms

- Modified version of the *singl-link* and *complete-link* algorithms
  - Able to cope with DL-based representations
  - Intentional cluster descriptions are given
- *LCS-based* algorithm
  - Inspired to single-link and complete-link algorithm
  - Works directly with intentional cluster descriptions
Single-link and Complete-link Algorithms

Figure B.1: Clustering process performed by the single-link algorithm. Cluster distances are given by the minimum distance among their elements.

Figure B.2: Clustering process performed by the complete-link algorithm. Cluster distances are given by the maximum distance among their elements.
LCS-based Algorithm

- Single and Complete link algorithm suffer of chaining effects in presence of noisy data
  - They cannot directly work with intentional cluster descriptions
- The LCS-based algorithm can overcome this drawback

\[
\text{LCS}\left( \text{LCS}(A',B'), \text{LCS}(C',D') \right)
\]

\[
\begin{align*}
\text{LCS}(A',B') & \quad \text{LCS}(C',D') \\
A & \quad B & \quad C & \quad D
\end{align*}
\]
Evaluating clustering algorithms: Setting

- Problem to solve: Given an ontology, cluster all the concepts (primitives and defined) in it
- Used 9 ontologies: People, University, family, FSM, S.-W.-M., Science, NTN, Newspaper, Wines
- Adopted measure: *IC-based dissimilarity measure*
- Evaluated the **internal quality** of the obtained clusters
  - Overall cluster (dis-)similarity \( S \) = \( 1/|S|^2 \sum_{c_i,c_j \in S} d(c_i,c_j) \)
  - where \( S \) is the considered cluster
  - Considered a dissimilarity measure
    - overall dissimilarity \( \rightarrow 0 \) \( \Rightarrow \) best cluster quality
    - overall dissimilarity \( \rightarrow 1 \) \( \Rightarrow \) worst cluster quality
Clustering Evaluation: Results

*Average overall clusters similarity for each considered ontology and with respect to the employed clustering algorithm*

### Service Discovery Evaluation

- hand-made service ontology: 256 concept descriptions, 116 service descriptions, 25 object properties
- Requested a service in the ontology
- Subsumption-based matching
- First match found is returned
- All services satisfying the request are returned

Similarity-based Learning Methods for the SW
A criterion for Ranking Services

- Generally services selected by the matching process are returned in a flat list
- Services selected by the matching process, have to be ranked w.r.t. certain criteria (a total order would be preferable)
- Ranking procedure based on the use of a semantic similarity measure for DL concept descriptions.
  - Provided services most similar to the requested service and satisfying both HC and SC of the request are ranked in the highest positions
  - Provided services less similar to the request and/or satisfying only HC are ranked in the lowest positions
Ranking Services using Constraint Hardness

[d’Amato et al. @ Sem4WS Workshop at BMP 2006]

given:

\[ S_r = \{S_r^{HC}, S_r^{SC}\} \] service request;
\[ S_p^i \ (i = 1, \ldots, n) \] provided services selected by \( \text{match}(KB, D_r, D_p^i) \);

for \( i = 1, \ldots, n \) do

\[ \text{compute } \bar{s}_i := s(S_r^{HC}, S_p^i) \]

let be \( S_r^{new} \equiv S_r^{HC} \cap S_r^{SC} \)

for \( i = 1, \ldots, n \) do

\[ \text{compute } \bar{s}_i := s(S_r^{new}, S_p^i) \]
\[ s_i := (\bar{s}_i + \bar{s}_i)/2 \]
A set of semantic (dis-)similarity measures for DLs has been presented
   - Able to assess (dis-)similarity between complex concepts, individuals and concept/individual
Experimentally evaluated by embedding them in some inductive-learning algorithms applied to the SW and SWS domains
- Realized an instance based classifier (K-NN and SVM) able to outperform concept retrieval and induce new knowledge
- Realized a set of clustering algorithms for improving the service discovery task
- A new ranking services procedure has been proposed based on the exploitation of a (dis-)similarity measure and constraint hardness
Future Works...

- Extention of Similarity and Dissimilarity Measures for most expressive DL such as *ALCN*
  - This could allow to cope with a wide range real life problems
- Explicitly treat roles contribution in assessing (dis-)similarity (currently only implicitly treated)
- Extension of the semi-distance measure for treating complex descriptions
  - Setting a method for determining the minimal discriminating feature set
- Make possible the applicability of the measures to concepts/individuals asserted in different ontologies (for using them in tasks such as: ontology matching and alignment)
The k-NN-based classifier could be extended with different answering procedures grounded on statistical inference (non-parametric tests based on ranked distances) in order to accept answers as correct with a high degree of confidence.

The k-NN-based classifier could be extended in a way such that the probability that an individual belongs to one or more concepts are given.

For clusters-based discovery process an heuristic (for finding the most appropriate service) could be useful for the cases in which, at the same level, more than one branch satisfy the matching test.

An incremental clustering method would be investigated for updating clusters when a new provided service is available.
Thank you.

For Attention.
